## **Cobalto**

### **Farmacocinética**

#### Exposición Oral

El consumo oral de cobalto origina absorción mediante el tracto gastrointestinal; los niveles de absorción varían entre el 18 al 97% en seres humanos y depende de la dosis y de la forma del cobalto así como también del estado nutricional de las personas expuestas. La absorción de cobalto tiende a aumentar en personas con deficiencia de hierro en su dieta y su eliminación en las heces es el método de excreción principal para exposiciones orales.

#### Exposición por Inhalación

Las partículas de cobalto inhalado se acumulan en el tracto respiratorio y el tamaño de la partícula determina si la acumulación ocurre en el tracto superior o inferior. Las partículas más grandes ( $> 2 \mu\text{m}$ ) tienden a acumularse en el superior, mientras que las partículas más pequeñas se transfieren al sistema respiratorio inferior. Desde los pulmones las partículas de cobalto se disuelven en el torrente sanguíneo o se transfieren al tracto gastrointestinal mediante acciones como la deglución. Aproximadamente el 50% del cobalto transferido al tracto gastrointestinal es realmente absorbido y el resto se elimina por medio de excreción fecal. Aproximadamente el 50% de la carga pulmonar inicial puede permanecer hasta 6 meses después de la exposición (Foster 1989, según se cita en ATSDR 1992).

#### Exposición Dérmica

La exposición dérmica de seres humanos (solo las manos) a polvo de metales duros (aproximadamente entre 5 a 15% de metal de cobalto, 95–85% de carburo de tungsteno) durante 90 minutos mostró un aumento en los niveles de cobalto en la orina en un orden de magnitud de hasta 60 horas después de la exposición. La absorción de  $2.2 \times 10^{-5}$  mg de  $^{60}\text{Co}/\text{kg}$  en forma de cloruro de cobalto a través de la piel intacta o escoriada de conejillos de indias reveló que la absorción es muy limitada a través de piel intacta ( $<1\%$ ), mientras que la absorción a través de piel escoriada fue de casi 80%. No se dispone de estudios sobre la distribución en seres humanos o animales después de una exposición dérmica al cobalto. La excreción de cobalto en hámsters ocurre principalmente en la orina dentro de 48 horas después de una sola exposición dérmica.

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

El cobalto es un elemento esencial para los seres humanos y es necesario para la producción de la vitamina B<sub>12</sub> (ATSDR 1992). Se encuentra en la mayoría de los tejidos corporales y las concentraciones más altas se ubican en el hígado, los riñones y los huesos. La vitamina B<sub>12</sub> es una coenzima de muchas reacciones biológicas incluyendo la producción de glóbulos rojos y el cobalto se ha utilizado para tratar la anemia. La Ración Alimenticia Recomendada (RDA) de la vitamina B<sub>12</sub> para adultos es 2.4 µg/día, (esta cantidad contiene 0.1 µg de cobalto) (ATSDR 1992). La exposición oral a altos niveles de cobalto se presenta en seres humanos que consumieron cerveza con sales de cobalto; en los años 60's las sales de cobalto se añadían a la cerveza para mejorar sus cualidades espumantes. Esta práctica se discontinuó desde ese entonces ya que causó varias muertes entre consumidores frecuentes (8 a 30 pintas por día) quienes consumieron dosis entre los 3 a los 10 mg de cobalto/por día. Efectos menos graves asociados con el consumo de cerveza con compuestos de cobalto incluyeron náuseas, vómitos y diarrea. El aumento de la producción de glóbulos rojos también ocurre en los seres humanos después de la exposición oral al cobalto. Se ha observado una reducción de la absorción del yodo en la glándula tiroides de seres humanos expuestos a dosis de corto tiempo de 1 mg/kg del peso corporal/día o dosis de largo tiempo de 0.54 mg/kg del peso corporal /día.

No se observaron efectos en el desarrollo de bebés nacidos de madres que tomaron medicamentos que contenían cobalto para regular su anemia durante el embarazo (Holly 1955, según se cita en ATSDR 1992). Tampoco se observaron efectos en el sistema reproductivo de las personas que murieron después de exponerse a altos niveles de cobalto en la cerveza. Se han observado algunos efectos en el sistema reproductivo de animales (efectos adversos en los ensayos y reducción de la duración del ciclo estral), sin embargo la importancia de estos efectos para los seres humanos no está clara ya que las dosis de cobalto utilizadas en los estudios fueron mucho más altas que las dosis a la que usualmente se exponen los seres humanos.

#### Exposición por Inhalación

La inhalación de cobalto puede afectar el sistema respiratorio y si se inhala en cantidades suficientes (0.003 mg/m<sup>3</sup>) se puede presentar irritación, respiración sibilante, asma y neumonía. La exposición ocupacional a concentraciones de cobalto de 0.038 mg/m<sup>3</sup> durante seis horas causó dificultades respiratorias, aunque estos niveles son aproximadamente de 10,000 a 100,000 veces más altos que la típica concentración en el aire en lugares abiertos. Las personas también pueden desarrollar sensibilidad al cobalto a través de la exposición ocupacional a concentraciones de

$\geq 0.007 \text{ mg/m}^3$  y exposiciones posteriores pueden ocasionar erupciones cutáneas o ataques de asma.

### Exposición Dérmica

Se reportó pérdida de peso en estudios realizados con animales con varios compuestos de cobalto. Se observó la necrosis del timo en ratas expuestas a  $19 \text{ mg/m}^3$  en forma de sulfato de cobalto y se encontró hiperplasia de los ganglios linfáticos mediastinales en ratones expuestos a  $11.4 \text{ mg/m}^3$ . Se reportaron efectos neurológicos tales como congestión de los vasos del cerebro/meninges en ratas y ratones expuestos a  $\geq 19 \text{ mg/m}^3$  en forma de sulfato de cobalto. Se reportaron también diversos impactos en el sistema reproductivo incluyendo atrofia testicular y disminución de la movilidad espermática en ratas y ratones expuestos a  $1.14\text{-}19 \text{ mg/m}^3$  durante tiempos de exposición intermedia y aguda, respectivamente.

### Dosis Referencial para la Exposición Oral Crónica (DR)

RIVM (2001) establece una IDT de  $0.0014 \text{ mg/kg}$  del peso corporal/día, este valor se dedujo en una evaluación previa de Vermeire (1991, según se cita en RIVM 2001) de acuerdo a un límite de migración para materiales de empaque. En el caso de los seres humanos el LOAEL más bajo reportado es  $0.04 \text{ mg/kg}$  del peso corporal/día, para cardiomiopatía después de una exposición oral intermedia. Se aplicó un factor de incertidumbre de 3 para variación entre seres humanos y un factor de 10 para extrapolación a un NOAEL, causando una IDT de  $0.0014 \text{ mg/kg}$  del peso corporal/día.

USEPA NCEA desarrolló una DR oral provisional de  $0.0003 \text{ mg/kg/día}$  (USEPA Región 3, 2009).

### Concentración Referencial para Exposición por Inhalación Crónica (CR)

No se dispone de una CR establecida por *Health Canada* (2009) o el sitio internet de USEPA IRIS, sin embargo el valor de la DR por inhalación provisional de USEPA NCEA es  $6\text{E-}6 \text{ mg/kg/día}$  (USEPA Región 3, 2009).

### Efectos Cancerígenos

No se ha demostrado que el cobalto cause cáncer en los seres humanos. Un estudio ocupacional informó un aumento en la incidencia de muertes por cáncer pulmonar entre trabajadores expuestos al cobalto en comparación con una población de control que no se había expuesto al cobalto. La diferencia entre los trabajadores expuestos y la población de control no se consideró estadísticamente significativa. Además la presencia de enfermedades pulmonares características asociadas con la exposición ocupacional al cobalto no se documentó, aunque la exposición concomitante a arsénico y níquel opacó los efectos observados. No se han observado tumores en seres

humanos con prótesis (es decir rodillas artificiales) que contenían aleaciones de cobalto.

La exposición al óxido de cobalto en hámsters no originó un aumento de la incidencia de tumores pulmonares en comparación con la población de control. La inyección intramuscular de óxido de cobalto originó la producción de tumores en ratas, pero no en ratones (Gilman 1962, según se cita en ATSDR 1992). Según los datos relacionados con animales, la Agencia Internacional para la Investigación del Cáncer clasificó al cobalto como posible agente cancerígeno para los seres humanos. Sin embargo actualmente no existe una clasificación de USEPA sobre carcinogenicidad (USEPA 2009).

#### Riesgo de Desarrollar Cáncer por Exposición Oral

Actualmente no se dispone de un factor de pendiente oral para el cobalto (USEPA 2009).

#### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No existe un factor de pendiente de inhalación de cobalto establecido por *Health Canada* (2004) o en el sitio internet de USEPA IRIS.

## **Cobre**

### **Farmacocinética**

#### Exposición Oral

La absorción del cobre ocurre principalmente a través del tracto gastrointestinal y la tasa relativa de absorción se relaciona con la dosis administrada. Por ejemplo cuando se administró a adultos una dieta baja en cobre (0.78 mg de cobre al día), 55.6% del cobre administrado se absorbió en el tracto gastrointestinal tal como se determinó con el uso de isótopos (ATSDR 1990). En el caso de adultos con una adecuada ingesta alimenticia de cobre (1.68 mg de cobre al día), se observó un 36.3% de absorción y en el caso de los adultos con una alta ingesta diaria de cobre (7.53 mg de cobre al día), solo se observó un 12.4% de absorción. La absorción de cobre en adultos es saturable y el porcentaje de absorción se reduce cuando la ingesta diaria de cobre aumenta. La retención total de cobre aumentó con la ingesta alimenticia y el equilibrio apropiado se mantiene incluso con la concentración más baja estudiada (0.78 mg de cobre al día). La absorción de cobre y el metabolismo disminuyen debido a la competencia de otros metales tales como el hierro y el zinc que buscan lugares de fijación en la metalotioneína, mientras que el molibdeno puede inhibir totalmente la retención del cobre (ATSDR 1990). El hígado es el principal órgano involucrado en la distribución de cobre en todo el cuerpo, y la distribución del cobre en otros tejidos ocurre a través del torrente sanguíneo. Al parecer la ceruloplasmina (proteína que pueden fijar 6 a 8 átomos de Cu (II)) y la albúmina sérica son los principales portadores (ATSDR 1990). Las concentraciones de cobre más altas se encuentran en el cerebro, los riñones, el corazón, el hígado y el páncreas (ATSDR 1990) y la principal trayectoria de eliminación del cobre en el hígado es la bilis, que representa aproximadamente el 80% del cobre que sale del hígado. El embarazo se asocia con un aumento en la retención de cobre y se debe probablemente a la disminución de la excreción biliar que resulta de los cambios hormonales que usualmente ocurren. La excreción urinaria y la sudoración son contribuyentes menores de la eliminación del cobre (ATSDR 1990).

#### Exposición por Inhalación

No se encontraron estudios sobre la tasa y la extensión de la absorción después de una exposición por inhalación de cobre en seres humanos. Datos limitados sobre los animales revelan la absorción de óxido en los capilares alveolares 3 horas después que expusieron ratas a polvo de soldadura en aerosol proveniente de alambres de cobre puro. Se estimó que la vida media del sulfato de cobre en los pulmones de las ratas es de 7.5 horas luego de la instilación intratraqueal de 20 µg de cobre por rata.

#### Exposición Dérmica

Los estudios con animales demuestran que el cobre atraviesa barreras dérmicas cuando se aplica con ciertos vehículos (por ejemplo, ácido salicílico o fenilbutazona).

Sin embargo los estudios sugieren que el cobre (cloruro de cobre > sulfato de cobre) no se absorbe bien a través de piel intacta y menos del 6% del cobre se absorbe después de una aplicación *ex vivo* en piel humana.

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

El cobre es un elemento esencial para los seres humanos y se encuentra ampliamente en todo el cuerpo, efectos adversos para la salud se pueden vincular a la deficiencia de cobre así como también a niveles excesivos del mismo; la deficiencia de cobre se demuestra con la anemia, neutropenia y anomalías óseas, pero raramente se observa en situaciones clínicas (ATSDR 1990). El cobre se considera esencial para el desarrollo de proteínas estructurales y enzimáticas, las enzimas que regulan la respiración celular, la desintoxicación de radicales libres, el metabolismo del hierro, la función neurotransmisora y la síntesis del tejido conectivo contiene cobre (ATSDR 1990). La regulación (activación y represión) de la transcripción de genes también necesita cobre (ATSDR 1990). El cuerpo regula las concentraciones de cobre mediante un proceso llamado homeostasis.

El cobre difícilmente es tóxico, a menos que se ingiera en grandes cantidades, los datos disponibles sobre su toxicidad asociada con el consumo oral de cobre se limitan a la ingesta de agua con concentraciones de cobre muy altas o intentos de suicidio que involucran al sulfato de cobre. La exposición crónica a agua potable que contenga (dosis aproximada de 0.06 mg de cobre/kg/día - 4.2 mg de cobre/día para un adulto de 70-kg) causó náuseas, vómitos y dolor abdominal poco después del consumo del agua (ATSDR 1990) y los problemas gastrointestinales se detuvieron después que se encontró un suministro de agua alternativo para las personas afectadas. Síntomas similares se observaron en pacientes que intentaron suicidarse (aunque la información sobre la dosis podría ser inexacta ya que la proporcionaron los mismos pacientes). Los efectos gastrointestinales se produjeron con dosis que van desde los 0.07 a los 1,421 mg de cobre/kg (4.9 a 99,470 mg de para un adulto de 70-kg) (ATSDR 1990).

La enfermedad de Wilson es un desorden genético asociado con el deterioro en el transporte del cobre del hígado hacia la bilis, originando un aumento de las concentraciones de cobre en el hígado, debido a que no pueden mantener la homeostasis. No se han observado efectos en el desarrollo de niños con madres que padecen la enfermedad de Wilson o en seres humanos sanos (ATSDR 1990). Los infantes y los niños menores de 1 año son inusualmente susceptibles a la toxicidad de cobre debido a que no han desarrollado el mecanismo homeostático para eliminar el cobre de cuerpo (ATSDR 1990). Otra condición genética que aumenta la susceptibilidad a la toxicidad del cobre es una deficiencia de la enzima glucosa-6-

fosfato deshidrogenasa. Las personas con una enfermedad hepática también son susceptibles a la toxicidad del cobre debido al papel crítico del hígado en la eliminación del cobre del cuerpo (ATSDR 1990).

Debido a que el cobre se considera un elemento esencial para los seres humanos, existen dos tipos de límites de exposición (a) la ingesta mínima diaria de manera que una persona no sufra de deficiencia de cobre y (b) las ingestas diarias máximas permisibles de manera que una persona no sufra debido a la toxicidad de cobre. Se ha encontrado toxicidad en el desarrollo de ratones, visones y hámsters que se alimentaron con una dieta rica en cobre o inyectados con cobre (ATSDR 1990). No se han observado efectos reproductivos en poblaciones de seres humanos expuestos a altos niveles de cobre. Los dispositivos intrauterinos que contienen cobre se utilizan como método anticonceptivo y estudios realizados con animales demuestran que los cables de cobre contenidos dentro de estos dispositivos son el agente contraceptivo.

#### Exposición por Inhalación

Trabajadores expuestos al polvo de cobre presentaron diversos síntomas respiratorios (irritación respiratoria que incluye tos, estornudos, dolor del tórax y goteo nasal), efectos gastrointestinales (anorexia, náuseas, diarrea), hematológicos (disminución de la hemoglobina y los eritrocitos), hepatomegalia, efectos endocrinológicos (adenoma hipofisario), reproductivos (impotencia) y otros efectos sistémicos (irritación ocular, escalofríos, fiebre, sequedad de la boca, dolor de cabeza. Se han observado efectos respiratorios leves (por ejemplo, engrosamiento alveolar) en hámsters, ratones y conejos expuestos a sulfato de cobre transportado por el aire (ATSDR 1990).

#### Exposición Dérmica

La exposición dérmica al cobre puede originar dermatitis (ATSDR 1990).

### **Dosis Referencial para la Exposición Oral Crónica (DR)**

#### Ingesta Diaria Mínima

La Organización Mundial de la Salud (OMS) determinó que la ingesta diaria mínima de cobre en adultos es de 0.020 mg de cobre/kg del peso corporal al día, lo cual equivale a 1.4 mg de cobre al día para un adulto promedio de 70 kg (USEPA 2004). En el caso de los niños, la OMS concluyó que la ingesta diaria mínima de cobre debe ser 0.050 mg/kg del peso corporal al día (equivalentes a 0.75 mg de cobre al día para un niño de 15 kg). Se determinó que la ingesta diaria mínima de cobre es la cantidad de cobre necesaria para que un niño o un adulto se desempeñen adecuadamente y que representa variables como las diferencias en la absorción, retención y almacenamiento del cobre.

### Ingesta Diaria Máxima Permissible

La ingesta diaria máxima permissible para adultos es algo incierta, pero se cree que está en el rango de 2-3 mg de cobre/día. La concentración máxima permissible considera estudios que indican que las personas expuestas a niveles más altos de cobre en el agua potable experimentaron molestias gastrointestinales temporales e incorpora un factor de seguridad de dos (es decir, la concentración máxima es la mitad del nivel en el cual se observaron efectos gastrointestinales). Actualmente solo existe información limitada sobre el nivel de la ingesta de cobre en los alimentos que podría causar un efecto adverso en la salud.

*Health Canada* (2009) estableció una ingesta diaria tolerable (IDT) de 0.09 mg/kg/día para niños pequeños y de 0.1 mg/kg/día para adultos y basó la ingesta diaria tolerable en una evaluación del Instituto de Medicina de los Estados Unidos (US IOM 2001) que determinó un nivel sin efectos adversos observados (NOAEL) de 10 mg/día para la función hepática de acuerdo a dos estudios con seres humanos sobre el consumo de tabletas de cobre. Se seleccionó un factor de incertidumbre (FI) de 1.0 debido a que el NOAEL se consideró representativo de la población general, no se consideró necesario un FI más alto debido a que los datos no indican efectos adversos ocasionados por el consumo diario de aproximadamente 10 mg/día de cobre en los alimentos e indican que el daño hepático a raíz de la exposición al cobre es poco común en poblaciones humanas con homeostasis de cobre normal. *Health Canada* (2009) ajustó el NOAEL basado en supuestos estándares de Canadá con respecto a la duración de las etapas de la vida y al peso corporal.

Actualmente no se dispone de una DR para el cobre elemental en el sitio internet de IRIS (USEPA 2004), sin embargo en la Tabla de Resumen de Evaluación de los Efectos para la Salud (HEAST) se incluye una DR oral de 0.04 mg/kg/día sobre la base de un LOAEL de una sola dosis oral de 5.3 mg en un estudio con seres humanos (con la ocurrencia de irritación gastrointestinal como el efecto crítico) (USEPA 1997).

### Concentración Referencial para la Exposición Crónica por Inhalación (CR)

Actualmente no se dispone de una CR para cobre elemental de USEPA (2004) o *Health Canada* (2009).

RIVM dedujo una concentración tolerable en el aire (TCA) de 0.001 mg/m<sup>3</sup> sobre la base de un NOAEC para los efectos en los pulmones y el sistema inmune de conejos a partir de un estudio sobre toxicidad a corto plazo y un factor de incertidumbre de 100 (10 cada uno para variabilidad intra y interespecies) y un factor de 6 (5/7 x 6/24) para ajustarse a la exposición continua.

### Efectos Cancerígenos

USEPA clasificó al cobre y a los compuestos de cobre como parte del grupo D, es decir no clasificables como agentes cancerígenos para los seres humanos, la clasificación se utiliza para sustancias en las cuales existen datos inadecuados con el fin de realizar una evaluación sobre carcinogenicidad. Específicamente en el caso del cobre y de los compuestos del cobre, no existen datos relacionados con seres humanos, los datos sobre bioensayos con animales son inadecuados y los resultados de los ensayos sobre mutagenicidad no son claros (USEPA 2004b).

### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone con un factor de pendiente oral para el cobre (USEPA 2004).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No se dispone de un valor de riesgo unitario por inhalación para el cobre (USEPA 2004).

## **Hierro**

### **Farmacocinética**

#### Exposición Oral

La Academia Nacional de Ciencias de los Estados Unidos (US NAS) estimó como la biodisponibilidad máxima del hierro en los alimentos es de 18%, de acuerdo a los cálculos de la absorción de hierro hemínico y no hemínico de diversos tipos de alimentos (US NAS, 2002). El principal mecanismo para regular los niveles de hierro en el cuerpo humano son los cambios en la cantidad de hierro absorbido por la mucosa gastrointestinal. La absorción de hierro en la dieta se afecta por: la cantidad de hierro almacenado en el cuerpo; la cantidad y el tipo químico de hierro en los alimentos ingeridos y factores alimenticios.

#### Exposición Dérmica/Por Inhalación

No se han encontrado estudios sobre la farmacocinética del hierro como resultado de una exposición dérmica o por inhalación.

### **Toxicidad**

#### Efectos no Cancerígenos

##### Absorción Oral

El hierro es un elemento esencial y un componente importante de diversas proteínas incluyendo a enzimas y la hemoglobina. Gran parte del hierro del cuerpo (aproximadamente 67%) se encuentra en la hemoglobina de los eritrocitos que circulan en el torrente sanguíneo, otro 25% se almacena en una forma rápidamente movable y el resto se encuentra en la mioglobina del tejido muscular y en enzimas necesarias para el metabolismo de oxidación (US NAS 2002).

Los efectos clínicos asociados con la deficiencia de hierro incluyen anemia, retraso en el desarrollo, daño cognitivo y resultados adversos en embarazos. Los efectos de una intoxicación aguda con hierro están bien documentados, principalmente como resultado de niños que ingieren accidentalmente suplementos de hierro, los síntomas incluyen malestar gastrointestinal y también alteraciones cardiovasculares, metabólicas, neurológicas y hepáticas. Es difícil establecer dosis tóxicas orales debido a que generalmente se calculan a partir de historias clínicas en situaciones de sobredosis. No se asocian efectos adversos en el desarrollo con la ingesta de suplementos de hierro durante el embarazo. Existe cierta controversia con respecto a si las personas con una capacidad normal de eliminar el hierro pueden sufrir una sobrecarga crónica debido a la ingesta oral, sin embargo el peso de la evidencia indica que es posible.

Un estudio (Looker 1998, según se cita en USEPA 2001) comparó la ingesta alimenticia de los estadounidenses (de 6 meses a 74 años) con los índices bioquímicos (niveles de ferritina sérica) a partir de la base de datos del segundo estudio nacional sobre salud y nutrición NHANES II), los resultados de la comparación muestran que los niveles de ingesta promedio del hierro (0.15 a 0.27 mg/kg-día) consumido por la población son suficientes para protegerla contra la deficiencia de hierro e insuficientes para causar efectos tóxicos, el estudio concluyó que el rango de 0.15 a 0.27 mg/kg/día representa un NOAEL para la ingesta diaria crónica de hierro.

Se ha observado toxicidad crónica de hierro en personas con trastornos que originan absorción excesiva de hierro, anomalías en la síntesis de la hemoglobina, anemia o transfusiones sanguíneas frecuentes. US NAS (2002) indica que el peso de la evidencia no sustenta una relación causal entre la ingesta elevada de hierro y enfermedades coronarias debido a que cinco de siete estudios no encontraron una asociación entre la ferritina sérica y las enfermedades coronarias (Aronow y Ahn 1996, Frey y Krider 1994, Magnusson 1994, Manttari y Stampfer 1993; según se cita en US NAS, 2002). Sin embargo US NAS (2002) también indicó que los niveles elevados de hierro no se podían descartar definitivamente como un factor de riesgo de contraer enfermedades coronarias debido a que las altas concentraciones de ferritina sérica y la ingesta alimenticia de hierro han demostrado ser factores de riesgo para infartos del miocardio en un estudio con hombre del este de Finlandia (Salonen, según se cita en US NAS, 2001). El estudio también demostró que altos niveles de colesterol en lipoproteínas de baja densidad (LDL) junto con niveles elevados de ferritina sérica son un factor de riesgo significativo para infartos del miocardio y concluyó que concentraciones excesivas de hierro promueven la oxidación de LDL, lo cual eleva el riesgo de sufrir infartos del miocardio (US NAS, 2001). Un nuevo análisis de las mismas personas cinco años después confirmó las conclusiones (Salonen 1994, según se cita en US NAS, 2002).

La Academia Nacional de Ciencias de los Estados Unidos (USEPA, 2002) desarrolló recientemente las siguientes directrices para la ingesta de hierro que dan cuenta de las diferencias fisiológicas durante las etapas de la vida.

#### Exposición Dérmica y por Inhalación

No se encontraron estudios sobre la toxicidad del hierro debido a exposiciones dérmicas o por inhalación.

#### Dosis Referencial Provisional para la Exposición Crónica Oral (DR)

No se dispone de una ingesta diaria tolerable ni con una CR para el hierro (*Health Canada* 2009, USEPA 2009).

USEPA no ha evaluado el hierro de manera formal y por lo tanto no ha desarrollado una dosis referencial oral (DR). En 1997, se indicó en tablas HEAST (Tablas de Resumen de los Efectos para la Salud) la insuficiencia de los datos para una evaluación cuantitativa de riesgos. El Centro de Apoyo Técnico del Superfondo del Centro Nacional de Evaluación Ambiental de USEPA dedujo una dosis referencial provisional para el hierro que se utilizará en las áreas del Superfondo de los Estados Unidos (USEPA 2006). La dosis referencial provisional es actualmente la única dosis referencial toxicológica disponible para la evaluación del hierro en lugares contaminados. Las propiedades toxicológicas del hierro no se han evaluado por ATSDR o la Organización Mundial de la Salud (OMS).

USEPA (2006) seleccionó un NOAEL de 0.15 a 0.27 mg/kg/día tomando como base un estudio sobre la ingesta alimenticia del hierro y el estado del hierro en la población de los Estados Unidos. El rango de la ingesta de hierro se considera suficiente para brindar protección contra la deficiencia de hierro, sin causar efectos tóxicos. USEPA seleccionó un estudio realizado por Frykman (1994) como crítico para determinar una DR provisional adecuada, en dicho estudio se demostró que el tratamiento diario con 60 mg de hierro elemental /diario durante un mes causó un aumento estadísticamente significativo de los efectos gastrointestinales en comparación con el placebo. Con el fin de determinar un LOAEL, se añadió la LOAEL de 60 mg de hierro elemental al día a la ingesta alimenticia media estimada de 11 mg de hierro elemental/día (NAS 2001), lo que resulta 71 mg de hierro elemental/día. Considerando un peso corporal de 70 kg (USEPA 1987), la LOAEL para la ingesta diaria de hierro es 1 mg/kg/día en los efectos gastrointestinales. Un factor de incertidumbre de 1.5 tomando en cuenta los siguientes factores: 1.5 para extrapolación de un LOAEL a un NOAEL, 1 para el uso de personas sensibles, 1 para la exposición durante menos de una vida y 1 para una base de datos adecuada; de esta forma la DR provisional (subcrónica y crónica) para el hierro es 0.7 mg/kg/día.

USEPA (2006) realizó la siguiente declaración que establece los límites de la dosis referencial provisional, la determinación de la dosis se enfoca en lo que se considera una ingesta oral segura de hierro para la población de seres humanos en general (es decir personas aparentemente normales y sanas). Los requisitos individuales y las reacciones adversas al hierro podrían ser altamente variables y pudiera ser que la DR provisional no proteja a las personas con trastornos hereditarios relacionados con el metabolismo del hierro u otras afecciones que pudieran afectar la homeostasis del hierro.

#### Nivel Máximo de Ingesta Tolerable (NM)

La Academia Nacional de Ciencias también determinó un nivel máximo de ingesta tolerable (NS) para el hierro de 45 mg/día, estableciendo el malestar gastrointestinal como punto final (US NAS, 2001). Con el fin de determinar el valor, se utilizó un

estudio con hombres y mujeres suecos que tomaban un suplemento de hierro (Frykman, según se cita en US NAS, 2001) y dejaron de tomarlo debido a sufrir de malestar gastrointestinal. De esta forma se determinó un LOAEL de 60 mg/kg, sin embargo el estudio no fue suficiente para determinar un NOAEL. Se calculó un LOAEL de ingesta de hierro total (no solo a partir del suplemento) añadiendo el LOAEL determinado en el estudio sueco (60 mg/día) a la ingesta diaria estimada de hierro en los alimentos para hombres y mujeres escandinavos (11 mg/día), dando como resultado un LOAEL de 70 mg/día. Se seleccionó un factor de incertidumbre de 1.5 para extrapolación de un LOAEL a un NOAEL, resultando un nivel máximo de ingesta de 45 mg/día. La conversión de la ingesta diaria máxima a una dosis diaria máxima, asumiendo un peso corporal de 70 kg, origina una dosis diaria máxima de 0.64 mg/kg/día.

#### Concentración Referencial para la Exposición Crónica por Inhalación (CR)

No se dispone de una concentración por inhalación tolerable ni una CR para el hierro (*Health Canada* 2009 USEPA 2009). En un intento por deducir una CR por inhalación crónica provisional, USEPA (2005a) concluyó que no existen datos adecuados sobre la inhalación en seres humanos o animales para la exposición al hierro o a compuestos de hierro orgánicos.

#### Efectos Cancerígenos

No se encontraron estudios que evalúen los efectos cancerígenos del hierro.

#### Riesgo de Desarrollar Cáncer por Exposición Oral

No se ha desarrollado un factor de pendiente oral para el hierro (*Health Canada*, 2009, USEPA 2009). USEPA (2005b) concluyó que la ausencia de datos adecuados que demuestren la carcinogenicidad en seres humanos impide deducir riesgos cancerígenos estimados cuantitativos para la ingesta de hierro u óxido de hierro.

#### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No se ha desarrollado un factor de pendiente de inhalación para el hierro (*Health Canada* 2009, USEPA 2009). USEPA (2005b) concluyó que la ausencia de datos adecuados que demuestren la carcinogenicidad para los seres humanos impide deducir riesgos cancerígenos estimados cuantitativos para la inhalación de hierro u óxido de hierro.

## Resumen

|                                   |               |                          |
|-----------------------------------|---------------|--------------------------|
| DR crónica oral                   | 0.7 mg/kg/día | NOAEL, USEPA, NCEA, 2006 |
| CR por inhalación                 | no disponible | USEPA 2009               |
| Factor de pendiente oral          | no disponible | USEPA, 2009              |
| Factor de pendiente de inhalación | no disponible | USEPA, 2009              |

*nota:* La DR crónica oral es un valor provisional.

## **Plomo**

### **Farmacocinética**

#### Exposición Oral

La absorción gastrointestinal del plomo depende de la persona (la edad, cantidad de alimento en el estómago, estado nutricional del calcio y hierro) así como también de las características del plomo ingerido (tamaño de la partícula, solubilidad y especies químicas). Al parecer la absorción es más alta en los niños (40-50%) que en los adultos (15%) y el estado nutricional de los niños también afecta la absorción (las deficiencias de hierro y calcio parecen aumentar la absorción de plomo). Los adultos expuestos a compuestos de plomo solubles al agua mostraron una absorción mucho mayor si el plomo no se administra con la ingesta simultánea de comidas (20 a 70%) en comparación con aquellos a los que se administra plomo junto con la ingesta comida (3 a 15 %). Al parecer el contenido mineral (calcio o fosfato) en la comida reduce efectivamente la absorción del plomo ingerido. La absorción de plomo de la tierra es menor a la absorción de plomo disuelto y también se reduce con la ingesta simultánea de comidas, los adultos que consumieron plomo de la tierra sin una comida absorbieron 26% de la dosis, mientras que aquellos que ingirieron el plomo de la tierra sin una comida absorbieron solo el 2.5% (ATSDR 2007). La absorción de plomo podría aumentar durante el embarazo en combinación con una mayor movilización del plomo desde los huesos y pudiera contribuir con un aumento de los niveles de plomo en sangre durante la segunda mitad del embarazo. El mecanismo de absorción del plomo pareciera ser saturable, ya que la absorción se reduce cuando la ingesta de plomo aumenta.

La distribución y eliminación de plomo coinciden independientemente de la ruta de exposición, lo que indica la participación de un mecanismo de transporte de plomo común. La distribución inicial de plomo a los tejidos depende de la velocidad con la que la sangre llega a los órganos objetivo y posteriormente el plomo se puede volver a distribuir entre los tejidos. El plomo en la sangre se encuentra en el componente celular de los glóbulos rojos. Se han desarrollado varios modelos farmacocinéticos con el fin de calcular la distribución del plomo entre los grupos de tejidos y así caracterizar las tasas de intercambio de plomo entre ellos. La distribución de plomo es esencialmente la misma en niños y adultos, aunque una porción más grande de carga corporal reside en los huesos de los adultos, la mayor parte de esta carga corporal se encuentra en los huesos (94% en los adultos y 73% en los niños) (ATSDR 2007); en consecuencia los niveles de plomo en la sangre pudieran permanecer elevados durante algún tiempo una vez que la exposición termine. El plomo no se distribuye de manera uniforme en todo el hueso y tiende a acumularse en los lugares que experimentan desarrollo óseo (calcificación) al momento de la exposición, la calcificación ósea en niños ocurre con mayor frecuencia en huesos trabeculares y en los adultos en los huesos trabeculares y

corticales. La mayor parte del plomo adquirido en la niñez no se fija permanentemente en los huesos debido a que el plomo se libera o excreta frecuentemente durante la resorción ósea. El plomo no se metaboliza o transforma en el cuerpo, aunque no forma complejos con varias proteínas. El plomo en los alimentos que no se absorbe por el tracto gastrointestinal, se elimina en las heces.

#### Exposición por Inhalación

Se estima que la deposición de las partículas de plomo transportado en el aire en adultos es de aproximadamente 30 a 50% y depende del tamaño de la partícula y de la tasa de ventilación. Se absorbe (aproximadamente 100%) de todas las especies químicas de plomo que se deposita en los pulmones.

#### Exposición Dérmica

Al parecer la absorción dérmica del plomo es mucho menos significativa que la absorción por inhalación o ingestión (0.06% a <0.3%).

### **Toxicidad**

#### Efectos no Cancerígenos

##### Exposición oral

Los efectos tóxicos del plomo no dependen de la ruta de exposición, la muerte puede ser el resultado de exposiciones a plomo extremadamente elevadas correspondientes a niveles de plomo en la sangre de 125 a 750 µg/dL (327 µg/dL en promedio) en los niños. Puede haber incluso efectos cardiovasculares tales como las lesiones cardíacas debido a las altas exposiciones. La evidencia actual no indica que el aumento del plomo en la sangre aumente la presión sanguínea. Las personas expuestas a envenenamiento por plomo en el trabajo usualmente exhiben una combinación de síntomas gastrointestinales tales como dolor abdominal, estreñimiento, náuseas y vómitos. El plomo afecta la síntesis del hemo causando una disminución de las concentraciones de hemoglobina en la sangre, pudiendo ocasionar anemia. Las altas exposiciones de plomo también pueden causar un color azulado en las encías, debilidad muscular y dolor de las articulaciones.

Los niveles de plomo en la sangre que van desde 60 a >100 µg/dL en trabajadores expuestos al plomo en el trabajo se han asociado a efectos en los riñones, los efectos reversibles incluyen disfunción de los túbulos proximales así como también aumento de sodio y excreción de ácido úrico y la exposición crónica causa efectos renales irreversibles más graves. Los efectos adversos en el metabolismo de la vitamina D parecen ocurrir en niños expuestos al plomo en forma crónica (niveles de plomo en la sangre de 33 a 120 µg/dL) con deficiencias concomitantes de calcio, fósforo y vitamina D, los niños parecen ser más susceptibles a efectos neurológicos causados por el

plomo ya que dichos efectos se presentan con niveles de plomo en la sangre más bajos. Los adultos muestran daños neurológicos incluso con niveles en sangre de 40 a 60 µg/dL, mientras que varios estudios indican que los niños con niveles de plomo en la sangre de aproximadamente 10 µg/dL no presentan daño neuroconductual (Cooney 1989). Según indican los estudios, cuando los niveles de plomo en la sangre se duplican de 10 a 20 µg/dL, existe una pérdida promedio de 1 a 3 puntos del coeficiente intelectual, observada en exámenes estándar para su determinación (ATSDR 2007). Las altas exposiciones ocupacionales de plomo pueden causar efectos en el sistema reproductivo tales como abortos, abortos espontáneos y partos de fetos muertos, no se han observado efectos en la tasa de abortos espontáneos con niveles de plomo en la sangre de 10 µg/dL y los niveles bajos de exposición al plomo no se han correlacionado con la ocurrencia de anomalías congénitas.

Los niños pequeños (menos de 5 años de edad) son altamente susceptibles a efectos en la salud causados por el plomo debido a que poseen mayor capacidad de absorberlo a través del tracto gastrointestinal en comparación con los adultos. El comportamiento de los niños pequeños como chuparse el dedo pulgar y comer tierra los expone aún más al plomo de la tierra y del polvo. Las deficiencias nutricionales, especialmente la deficiencia de zinc, pudieran aumentar algunos de los efectos tóxicos del plomo. Las mujeres también podrían estar más expuestas al plomo ya que el embarazo, la lactancia y la osteoporosis hacen que los huesos pierdan minerales (se rompan) y con ello liberen plomo de los huesos hacia el torrente sanguíneo y causen un aumento de las cargas de plomo en el cuerpo y el aumento del plomo en la madre puede transferirse al feto a través de la placenta.

#### Exposición por Inhalación

Hombres adultos expuestos a partículas de plomo (0.003 o 0.01 mg lead/m<sup>3</sup>) durante 23 horas al día durante un periodo de 3 a 4 meses mostraron una disminución de las enzimas involucradas en la biosíntesis del hemo (ATSDR 2007).

#### Exposición Dérmica

Se encontraron estudios limitados sobre los efectos en seres humanos o animales después de una exposición dérmica a plomo inorgánico. La absorción dérmica de plomo inorgánico generalmente se considera mucho menor que la absorción que ocurre por inhalación o exposición oral (ATSDR 2007).

#### Ingesta Diaria Tolerable (IDT) y Dosis Referencial (DR) para la Exposición Oral Crónica

La ingesta diaria tolerable oral de plomo es 3.6E-3 mg/kg del peso corporal/día basada en un valor de ingesta diaria aceptable (IDA) deducida a partir de estudios metabólicos con infantes, que encontraron un NOAEL de 3E-3 a 4E-3 mg/kg del peso corporal con efectos críticos como el aumento de los niveles de plomo en la sangre y de la carga

corporal de plomo (*Health Canada* 2002). Se aplicó un factor de incertidumbre bajo de <2 basado en el nivel conservador de este punto final, la calidad de los datos metabólicos y el uso de una sub-población altamente susceptible (*Health Canada* 2002).

USEPA (2009) determinó que podrían presentarse efectos por la exposición al plomo, especialmente cambios en las enzimas de la sangre y en el desarrollo neurológico de los niños, con niveles de plomo en la sangre tan bajos que esencialmente no presenten un umbral. Como resultado de ello, USEPA considera inapropiado deducir un valor referencial de toxicidad oral (es decir DR) para el plomo.

#### Concentración Tolerable (CT) y Concentración Referencial (CR) para la Exposición Crónica por Inhalación

No se dispone de un valor para la concentración por inhalación tolerable de plomo de *Health Canada* (*Health Canada* 2009).

USEPA (2009) también determinó que es inadecuado deducir un valor referencial de toxicidad por inhalación (es decir, CR) para el plomo.

#### Efectos Cancerígenos

*Health Canada* clasificó al plomo en el grupo IIIB, es decir, posible agente cancerígeno para los seres humanos, sobre la base de datos inadecuados con respecto a los seres humanos y evidencia limitada relacionada con los animales (*Health Canada* 2009).

USEPA lo clasificó en el grupo B2, es decir probable agente cancerígeno para los seres humanos, sobre la base de los datos disponibles relacionados con los animales, los cuales indican que el plomo ingerido es cancerígeno, siendo los tumores renales el tipo de tumor más prevalente. Estudios epidemiológicos con seres humanos indican que el plomo podría causar un aumento de la incidencia del cáncer de pulmón y vejiga en general (ATSDR 2007), sin embargo estos estudios también carecen de información cuantitativa sobre la exposición al plomo y no se examinaron los factores que inducen a confusión ni la exposición concomitante a otros metales.

Actualmente USEPA (2009) no recomienda calcular el riesgo de desarrollar cáncer debido a la exposición al plomo utilizando procedimientos estándares para la evaluación de riesgos debido a la farmacocinética especial del plomo.

#### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone de una dosis tumorigénica o factor de pendiente oral para el plomo o compuestos del plomo (*Health Canada* 2009, USEPA 2009).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No se dispone de una concentración tumorigénica o factor de pendiente de inhalación para el plomo o sus compuestos (*Health Canada* 2009, *USEPA* 2009).

## ***Manganeso***

### **Farmacocinética**

#### **Exposición Oral**

El manganeso se encuentra usualmente en el tejido humano, la sangre, el suero y la orina. Los humanos adultos generalmente mantienen niveles constantes de manganeso en los tejidos, independientemente de la ingesta del mismo. La absorción y excreción de manganeso se regulan, la absorción ocurre principalmente a través de las rutas de exposición oral y por inhalación, la tasa de absorción en todo el tracto gastrointestinal es variable, usualmente entre 3 a 5% en los seres humanos (ATSDR 2000). Al parecer no existe diferencia en la absorción en todo el tracto gastrointestinal si el manganeso se consume en los alimentos o en el agua (ATSDR 2000) y podría depender de la edad ya que estudios demuestran una mayor absorción en niños pequeños que en adultos. Los niveles alimenticios del hierro también influyen la absorción de manganeso, ya que niveles bajos de hierro originan un aumento de la absorción de manganeso. El metabolismo del manganeso no se conoce muy bien en sistemas humanos, pero al parecer involucra a la oxidación del manganeso Mn(II) a Mn(III). La excreción ocurre principalmente mediante la bilis, aunque otras rutas de eliminación incluyen la orina, la leche materna y el sudor, el manganeso se elimina de la sangre mediante el hígado, en donde se conjuga con bilis y se excreta al intestino y se elimina con las heces.

#### **Exposición por Inhalación**

Los pulmones y el tracto gastrointestinal pueden absorber el manganeso luego de la inhalación de su polvo, sin embargo no se conocen las tasas relativas de absorción (ATSDR 2000).

#### **Exposición Dérmica**

Se espera que la absorción de manganeso a través de piel intacta sea extremadamente limitada (ATSDR 2000).

### **Toxicidad**

#### **Efectos no Cancerígenos**

#### **Exposición Oral**

El manganeso es un elemento esencial para los seres humanos y se encuentra extensamente en todo el cuerpo, los efectos adversos para la salud se pueden vincular tanto con la deficiencia como con el exceso de manganeso. El manganeso se requiere para la mineralización ósea, el metabolismo de proteínas y de la energía, la regulación metabólica y la protección celular frente a los radicales libres. El manganeso es

también un componente de metaloenzimas y puede actuar como un activador enzimático (ATSDR 2000).

#### Exposición por Inhalación

La exposición crónica a altos niveles de manganeso ha causado daños neurológicos permanentes en mineros expuestos a nivel ocupacional (ATSDR 2000). Las exposiciones crónicas a concentraciones de manganeso más bajas han originado la pérdida de coordinación y del equilibrio, así como la disminución de la capacidad de realizar movimientos rápidos con la mano (ATSDR 2000). La inhalación que contiene material particulado pudiera originar también una respuesta inflamatoria en los pulmones (ATSDR 2000).

#### Exposición Dérmica

Se ha descubierto que las formas orgánicas de manganeso (maneb y mancozeb) causan reacciones alérgicas de dermatitis por contacto.

#### Dosis Referencial para la Exposición Oral Crónica (DR)

*Health Canada* (2009) desarrolló una ingesta diaria tolerable para el manganeso de 0.1 mg/kg/día para niños pequeños receptores y 0.2 mg/kg/día para adultos receptores.

USEPA desarrolló una DR de 0.14 mg/kg/día basada en una recopilación de evaluaciones de ingestas alimenticias de manganeso típicas. En 1989 la Comisión Americana de Alimentos y Nutrición del Consejo Nacional de Investigación (NRC) determinó una ingesta alimenticia diaria segura estimada de 2 a 5 mg/día e indicó que una ingesta ocasional de 10 mg/día podría ser segura. Posteriormente algunos nutricionistas han indicado que el nivel del NRC de 2 a 5 mg/día pudiera ser demasiado bajo de acuerdo a recientes cambios en la dieta que incluyen un mayor consumo de carnes y alimentos procesados y menos granos enteros, y recomendaron niveles de 3.5 a 7 mg/día para evitar niveles de manganeso por debajo del nivel óptimo en la población (USEPA 2004). La Organización Mundial de la Salud también examinó los niveles de manganeso en la dieta de los adultos y el promedio diario varía de 2.0 a 8.8 mg/día. La Organización Mundial de la Salud llevó a cabo estudios sobre el equilibrio del manganeso y encontró que 2 a 3 mg/día es adecuado y que 8 a 9 mg/día es "seguro" para poblaciones de adultos (USEPA 2004). Generalmente las concentraciones altas de manganeso en la dieta se asocian con un alto consumo de cereales de grano entero, nueces, verduras de hojas verdes y té. Es importante indicar que la biodisponibilidad del manganeso en dietas vegetarianas es menor que en dietas no vegetarianas debido a la formación de complejos insolubles en los intestinos (USEPA 2004). Otros estudios indican que las dietas típicas en los Estados Unidos, Inglaterra y Holanda contienen concentraciones de manganeso de 2.3 a 8.8 mg/día. Tomando como base una recopilación de estudios en seres humanos, USEPA

recomienda el uso de 10 mg/día como NOAEL crónico. La DR corresponde a 0.14 mg/kg/día según una corrección para un adulto de 70 kg. Se aplicó un factor de incertidumbre de 1 al NOAEL crónico debido a que el NOAEL se derivó de una muestra representativa de muchas poblaciones grandes de seres humanos y a que el manganeso es un elemento esencial.

Un estudio epidemiológico del manganeso en el agua potable y en la dieta de tres áreas al noroeste de Grecia demostró efectos neurológicos en poblaciones expuestas al manganeso, sin embargo la cantidad exacta en el agua y la dieta no se pudo cuantificar, imposibilitando con ello el desarrollo de una relación cuantitativa dosis-respuesta. Las concentraciones estimadas de manganeso en la dieta y el agua fluctúan entre los 5 y 15 mg/día (USEPA 2004). Debido a la posibilidad de que existan efectos neurológicos con concentraciones de manganeso cercadas al NOAEL crónico, USEPA también recomienda sustraer la ingesta alimenticia básica de manganeso (5 mg/día; USEPA Region 9 2002) de la DR y utilizar un factor de modificación de tres cuando se realicen evaluaciones de riesgo con fuentes de manganeso no alimenticias (es decir manganeso en la tierra o en el agua potable). La substracción del manganeso alimenticio básico y el uso de un factor de modificación de tres resultan en una DR de 0.024 mg/kg/día.

La Organización Mundial de la Salud dedujo una ingesta diaria tolerable (IDT) de 0.06 mg/kg del peso corporal para el manganeso, según estudios sobre la dieta de los seres humanos en donde un valor máximo de 11 mg/día para la ingesta se consideró como un NOAEL. El NOAEL de 11 mg/día dividió por un factor de incertidumbre de 3 (para permitir el posible aumento de la biodisponibilidad del manganeso derivado del agua) y por un peso corporal adulto de 60 kg (OMS 2004; 2008).

#### Concentración Referencial para la Exposición Crónica por Inhalación (CR)

USEPA desarrolló una CR de  $5E-5$  mg/m<sup>3</sup> para el manganeso, tomando como base la disminución de la función neuroconductual descubierta en hombres en Bélgica expuestos en forma ocupacional al polvo de dióxido de manganeso en una fábrica de baterías. Dicha disminución involucró un tiempo de reacción visual significativamente más lento y el control errático del movimiento mano-antebrazo en la población expuesta en forma ocupacional en comparación con los sujetos de control. Los trabajadores de la fábrica se expusieron a una concentración de polvo respirable integrado (PRI), que se calculó multiplicando exposiciones ocupacionales con un promedio de tiempo ponderado de 8 horas para varias clasificaciones de trabajo por el número de años que las personas habían trabajado en la fábrica. Se determinó un LOAEL de 0.15 mg/m<sup>3</sup> dividiendo la media métrica geométrica del PRI por la duración promedio de la exposición de los trabajadores, se ajustó el LOAEL (HEC) para una exposición continua (es decir, en lugar de 5 días de trabajo/semana) y es 0.05 mg/m<sup>3</sup>. Se evaluó muchos otros estudios ocupacionales y se calcularon valores de LOAEL más bajos, sin

embargo la exposición al manganeso en otros estudios ocupacionales corresponde al resultado de una mezcla desconocida de compuestos de manganeso y las concentraciones variaron con el tiempo; por lo que USEPA decidió utilizar un LOAEL de  $0.05 \text{ mg/m}^3$  con el fin de deducir una CR para el manganeso.

Se aplicó un factor de incertidumbre de 1000 al LOAEL para entonces deducir una CR de  $5\text{E-}5 \text{ mg/m}^3$ . El factor de incertidumbre se compone de: un factor de 10 para representar las sub-poblaciones sensibles, un factor de 10 para representar el uso de un LOAEL y así establecer la CR y un factor de 10 para representar las limitaciones de la base de datos que reflejen la exposición no crónica, la falta de datos de desarrollo y las diferencias no cuantificadas en la toxicidad de diferentes formas de manganeso (USEPA 2004). La confianza en la CR es media, reflejándose la confianza media en el estudio principal y la base de datos.

#### Efectos Cancerígenos

*Health Canada* (1996) no ha evaluado la carcinogenicidad del manganeso.

USEPA clasificó al manganeso como un cancerígeno del grupo D, es decir no clasificable en cuanto a la carcinogenicidad para los seres humanos debido a la falta de datos referentes a seres humanos y datos inadecuados de estudios con animales. Se realizaron varios estudios con roedores, sin embargo ninguno de los animales desarrolló un aumento significativo en el número de tumores después de la administración del manganeso en comparación con los controles o en un caso, la evidencia de una relación con la dosis se consideró marginal. Actualmente no se dispone de estimados cuantitativos para los factores de la pendiente o los valores de riesgo unitario.

#### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone de un factor de pendiente oral para el manganeso (*Health Canada* 2004, USEPA 2004).

#### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No se dispone de un factor de pendiente de inhalación para el manganeso (USEPA 2004).

## Resumen

|                                   |                        |                      |            |
|-----------------------------------|------------------------|----------------------|------------|
| IDT oral                          | 0.06 mg/kg/día         | derivada del NOAEL   | OMS 2008   |
| CR por inhalación                 | 5E-5 mg/m <sup>3</sup> | daño neuroconductual | USEPA 2004 |
| factor de pendiente oral          | no disponible          |                      | USEPA 2004 |
| factor de pendiente de inhalación | no disponible          |                      | USEPA 2004 |

\* USEPA recomienda sustraer la ingesta alimenticia básica de manganeso y utilizar un factor de modificación de tres cuando se evalúan fuentes de manganeso no alimenticias, dando como resultado una DR modificada de 0.024 mg/kg/día.

## **Mercurio**

### ***Farmacocinética***

#### Exposición Oral

Las principales fuentes de exposición al mercurio para la población en general son el consumo de pescado, que contiene metilmercurio, y la liberación del mercurio elemental de los empastes dentales (ATSDR 1999). Los datos de seres humanos y animales generalmente se limitan a la exposición por inhalación de vapores de mercurio metálico y a la exposición oral a compuestos de mercurio inorgánico y orgánico. El mercurio metálico es altamente lipofílico y se difumina rápidamente en la sangre hacia los principales órganos objetivos tales como la sangre, el cabello, los dientes, los riñones, el cerebro, los pulmones, el hígado y el bazo (ATSDR 1999). La ingesta de cantidades pequeñas de mercurio metálico como el volumen encontrado en un termómetro estándar (aproximadamente 0.1 mL o 1 g) no produce síntomas de intoxicación (ATSDR 1999), los informes sobre la ingesta de cantidades sustanciales de mercurio elemental indican que la absorción es insignificante (<0.01%) (ATSDR 1999). Cierta cantidad de estudios con animales indica una absorción oral de mercurio inorgánico en un rango de 10 a 30% y la tasa en ratas y ratones depende de diversos factores (por ejemplo pH intestinal, disociación de compuestos, edad y dieta). En estudios con animales el mercurio inorgánico tiende a distribuirse al hígado y a los riñones, también se encontraron cantidades más pequeñas en el cerebro y la retención fue más prolongada en este tejido. A pesar de que los compuestos de mercurio inorgánico no se transfieren con facilidad de la sangre de una mujer embarazada al feto, existe una transferencia eficiente de mercurio inorgánico de la sangre a la leche materna. Luego de la exposición al mercurio metálico, la eliminación puede ocurrir mediante la orina, las heces y el aire respirado.

Los compuestos de mercurio orgánico se absorben con más facilidad por exposición oral que los compuestos de mercurio inorgánico, siendo el metilmercurio el que se absorbe con más facilidad a través del tracto gastrointestinal (ATSDR 1999). La absorción y biodisponibilidad del metilmercurio en los alimentos, específicamente en los pescados y en el pan, se pueden afectar por otros componentes alimenticios. El metilmercurio se distribuye rápidamente a todos los tejidos, incluyendo el cerebro y el feto, y los niveles más altos se encuentran en los riñones, también se puede secretar en la leche materna. La desmetilación ocurre en el cerebro, así como en otros órganos, incluyendo los riñones y el hígado, y pudiera contribuir sustancialmente a las altas concentraciones de mercurio inorgánico en el cerebro. Los compuestos de mercurio orgánico se excretan principalmente mediante las heces en los seres humanos.

### Exposición por Inhalación

La retención de mercurio después de la exposición al vapor de mercurio elemental liberado del mercurio líquido es de aproximadamente 70 a 80% en tejidos humanos. No se encontraron estudios sobre la absorción de compuestos de mercurio orgánico (por ejemplo fenilmercurio o metilmercurio) en seres humanos o animales mediante exposición por inhalación.

### Exposición Dérmica

La absorción dérmica de vapor de mercurio metálico representa un peligro ocupacional muy bajo en comparación con la exposición por inhalación (ATSDR 1999). Se estima que la ruta dérmica absorbe aproximadamente el 2.6% de la cantidad absorbida por el pulmón. No se encontró información disponible sobre la absorción dérmica del mercurio metálico líquido, pero a menos que la superficie de la piel esté dañada, se espera que sea mínima (ATSDR 1999). La absorción dérmica de la especie de dialquil mercurio es casi completa (es decir 100%).

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

##### *Mercurio Orgánico e Inorgánico*

Los principales órganos, objetivo de la toxicidad después de la exposición oral a mercurio inorgánico y orgánico son los riñones y el sistema nervioso central, respectivamente. Los principales efectos del mercurio orgánico en el sistema nervioso central incluyen alteraciones motoras y disfunción sensorial, en el área de Minamata en Japón y en Irak se reportó un brote general de trastornos neurológicos asociados con la ingesta de metilmercurio (ATSDR 1999) y los síndromes neurológicos observados en estas poblaciones altamente expuestas incluyen sensación de hormigueo en las extremidades, daños en la visión periférica, audición, gusto y olfato, problemas de dicción, debilidad muscular; irritabilidad, pérdida de la memoria, depresión y dificultades para dormir. La exposición prenatal al metilmercurio en roedores ha demostrado causar retrasos en el desarrollo y daños en la función motora.

### Exposición por Inhalación

##### *Mercurio Metálico*

Los síntomas reportados con mayor frecuencia después de la exposición a vapores de mercurio metálico en altas concentraciones incluyen tos, disnea y rigidez o quemazón en el pecho (ATSDR 1999), en casos más graves se observa malestar respiratorio, edema pulmonar y neumonía. Otros órganos objetivo principales para la toxicidad inducida por inhalación de mercurio metálico son los riñones, el sistema nervioso central y el sistema gastrointestinal. Los conejos expuestos al vapor de mercurio durante diferentes periodos de tiempo demuestran efectos neurológicos como

temblores, irritabilidad, nerviosismo, insomnio, pérdida de memoria, cambios neuromusculares, dolores de cabeza, polineuropatía y déficits de desempeño en pruebas de la función cognitiva.

#### *Mercurio Orgánico e Inorgánico*

La exposición al mercurio orgánico por inhalación es extremadamente rara, sin embargo en un granjero que había manejado grano con cantidades desconocidas de acetato de fenilmercurio; se observó disnea, depresión respiratoria y respiraciones frecuentemente obstruidas por mucosidad (ATSDR 1999). En varios estudios de casos con seres humanos expuestos a compuestos de mercurio orgánico, se reportan efectos gastrointestinales, similares a los observados por la exposición a mercurio metálico,

#### Exposición Dérmica

La exposición ocupacional aguda y crónica a mercurio inorgánico originó dermatitis por contacto (ATSDR 1999), la aplicación de ungüento con mercurio amoniacal en la piel en niños originó picazón, rubefacción, hinchazón y conjuntivitis, una mujer expuesta a aplicaciones tópicas de una crema que contenía 17.5% de cloruro de amonio mercurico durante 18 años mostró temblores leves, ansiedad y depresión. La exposición dérmica a metilmercurio o fenilmercurio en seres humanos pudiera causar erupciones y ampollas en la piel (ATSDR 1999).

#### Ingesta Diaria Tolerables (IDT) y Dosis Referencial (DR) para la Exposición Crónica Oral

No se dispone de una DR de USEPA para exposición oral crónica a mercurio elemental (USEPA 2004), sin embargo USEPA (2004) desarrolló una DR por cloruro mercurico de  $3E-4$  mg/kg/día, según los resultados de varios estudios realizados con ratas (estudios subcutáneos y alimentación) que se utilizaron para recomendar un nivel equivalente en agua potable (0.010 mg/L). Posteriormente el nivel equivalente en agua potable se utilizó para volver a calcular una concentración con dosis referencial tomando como base una tasa de ingesta de agua potable de 2L al día y un peso corporal adulto de 70 kg. Se aplicó un factor de incertidumbre de 1000 al LOAEL deducido a partir de estudios con ratas, incluyendo (1) un factor de 10 por el uso de ratas marrones de Noruega en el estudio, (2) un factor de 10 por el uso de un LOAEL en lugar de un NOAEL para deducir la DR y (3) un factor de 10 para representar el uso de estudios subcrónicos, la extrapolación interespecies y las poblaciones humanas sensibles. La confianza en la base de datos y la DR es alta.

Para *Health Canada*, la ingesta oral diaria tolerable de mercurio inorgánico corresponde a  $3E-4$  mg/kg del peso corporal/día y se basa directamente en la DR para cloruro mercurico desarrollada por USEPA (CCME 1999).

La Organización Mundial de la Salud dedujo una ingesta diaria tolerable (IDT) de 2 µg/kg del peso corporal para el mercurio inorgánico (OMS 2000). La IDT se basó en un estudio realizado durante 26 semanas en donde se determinó un NOAEL de 0.23 mg/kg del peso corporal al día para los efectos renales en ratas. El valor se ajustó para una dosis de 5 días por semana y se aplicó un factor de incertidumbre de 100 (variación interespecies e intraespecies).

#### Concentración Tolerable (CT) y Concentración Referencial (CR) para la Exposición Crónica por Inhalación

La CR para mercurio elemental es  $3\text{E-}4 \text{ mg/m}^3$  y se basa en diversos estudios sobre inhalación ocupacional en seres humanos enfocados en la ocurrencia de temblores en las manos, aumento de trastornos de la memoria y evidencia de disfunción autonómica como puntos finales de efectos críticos. Se determinó un LOAEL de  $0.025 \text{ mg/m}^3$  tomando como base concentraciones por exposición promedio de aproximadamente  $0.025\text{-}0.03 \text{ mg/m}^3$ , durante un periodo de unos 15 años. El LOAEL se basa en una exposición ocupacional con una concentración en el aire y un promedio de tiempo ponderado de 8 horas y extrapolación a partir de los niveles sanguíneos. La CR contiene un factor de incertidumbre de 30, el cual incluye un factor de 10 debido a la protección de las sub-poblaciones humanas sensibles y el uso de un LOAEL en lugar de un NOAEL y un factor de 3 debido a la falta de desarrollo y a los estudios reproductivos en la base de datos.

#### Efectos Cancerígenos

*Health* Canada no ha clasificado la carcinogenicidad del mercurio inorgánico (CCME 1999).

El mercurio elemental se clasifica como un cancerígeno del grupo D, es decir no clasificable debido a la existencia de datos inadecuados con respecto a los seres humanos y animales, según los datos inadecuados existentes con respecto a los seres humanos y animales. Los estudios epidemiológicos se limitan a la presencia de factores que inducen a confusión y a las exposiciones concomitantes a múltiples químicos y no se ha demostrado una correlación entre la exposición al vapor de mercurio elemental y la carcinogenicidad.

USEPA clasifica al cloruro de mercurio como un cancerígeno del grupo C, es decir posible agente cancerígeno para los seres humanos, debido a la falta de datos con respecto a los seres humanos y a la limitada evidencia en roedores (USEPA 2004).

#### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone de una dosis tumorigénica para el mercurio inorgánico ni factores de la pendiente oral para el mercurio elemental y el cloruro de mercurio por parte de *Health*

Canada y USEPA, ya que los datos sobre carcinogenicidad en seres humanos y animales se consideran limitados o inadecuados (*Health Canada* 2004, USEPA 2004).

#### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No se dispone de una concentración tumorigena para el mercurio inorgánico ni factores de la pendiente de inhalación para el mercurio elemental y el cloruro de mercurio por parte de *Health Canada* y USEPA, ya que los datos sobre carcinogenicidad en seres humanos y animales se consideran limitados o inadecuados (*Health Canada*, 2004; USEPA, 2004).

#### **Resumen**

|                                              |                           |                      |            |

## ***Molibdeno***

### **Farmacocinética**

#### Exposición Oral, Dérmica y por Inhalación

Actualmente no se dispone de información farmacocinética para el molibdeno.

### **Toxicidad**

#### Exposición no Cancerígena

#### Exposición Oral, Dérmica y por Inhalación

Actualmente no se dispone de información sobre la toxicidad no cancerígena en general para el molibdeno.

#### Ingesta Diaria Tolerable (IDT) y Dosis Referencial (DR) para la Exposición Oral Crónica

Para la ingesta diaria tolerable oral del molibdeno existe un valor de 0.023 mg/kg/día para niños pequeños y de 0.028 mg/kg/día para adultos establecida por Health Canada (Health Canada 2009).

USEPA (2004) desarrolló una dosis referencial para la exposición crónica oral al molibdeno de 5E-3 mg/kg/día, a partir de un estudio con una exposición alimenticia en seres humanos durante 6 años o de por vida la cual se enfocó en el aumento de los niveles de ácido úrico en el torrente sanguíneo como un efecto crítico (USEPA 2004). No se estableció un NOAEL, pero el valor del LOAEL corresponde a 0.14 mg/kg/día. El factor de incertidumbre general de 30 se compone por un factor de 3 debido a la protección de sub-poblaciones sensibles y un factor de 10 por el uso de un LOAEL de un estudio con una exposición de seres humanos por largo tiempo. La confianza general en la DR es media debido al uso de un estudio principal basado en un examen de los efectos físicos únicamente generales de una enfermedad tipo gota, con un análisis parcial de la química de la sangre para parámetros normalmente asociados con la gota y no con un análisis exhaustivo (USEPA 2004).

#### *Concentración tolerable (CT) y concentración referencial (CR) debido a una exposición crónica por inhalación*

No se dispone de un valor para la concentración por inhalación tolerable de molibdeno establecida por Health Canada (Health Canada 2009).

Actualmente no se dispone de un valor de CR por parte de USEPA para el molibdeno (USEPA 2004).

RIVM (2001) estableció una concentración tolerable en aire (CTA) de 0.012 mg/m<sup>3</sup>, basada en estudios por inhalación semi-crónica en ratas y ratones. La CTA se derivó

de acuerdo a un NOAEC ajustado de 12 mg/m<sup>3</sup> con un factor de seguridad de 1000 con el fin de representar la variabilidad interespecies e intraespecies y la extrapolación de una exposición semi-crónica a crónica.

### Efectos Cancerígenos

*Health Canada* (1993) y USEPA (2004) no han clasificado al molibdeno en cuanto a su carcinogenicidad en seres humanos.

### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone de una dosis tumorigénica (DT<sub>05</sub>) ni un factor de pendiente oral para el molibdeno por parte de *Health Canada* (2009) o USEPA (2004).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No se dispone de una concentración tumorigénica (CT<sub>05</sub>) ni un factor de pendiente de inhalación para el molibdeno por parte de *Health Canada* (2009) o USEPA (2004).

### **Resumen**

|                                   |                         |                                     |                           |

## **Níquel**

### **Farmacocinética**

#### Exposición Oral

Estudios examinaron la absorción de níquel en seres humanos y encontraron que el sulfato de níquel es 40 veces más biodisponible si es administrado en agua en lugar de junto con la ingesta de alimentos (ATSDR 1997), la biodisponibilidad del níquel también aumenta cuando se administra en un refresco, pero no cuando se administra con leche, café, té o jugo de naranja (ATSDR 1997). Se encontró que los niveles de níquel en suero son elevados en sujetos que no habían ingerido alimentos antes de la administración del níquel en agua potable, sin embargo esto no ocurría en personas que recibían níquel en los alimentos, debido a que los mismos tienden a reducir la biodisponibilidad del níquel. Se descubrió que en algunas personas sensibles al níquel las concentraciones de suero se habían reducido y las concentraciones de níquel en la orina habían aumentado con mayores concentraciones de níquel administrado (ATSDR 1997). Esto pudiera ser una indicación de que algunas personas sensibles al níquel reducen su absorción como respuesta al aumento de la ingesta de níquel. La mayor parte del níquel se excreta por las heces, aunque el absorbido por el tracto gastrointestinal se excreta en la orina y en estudios comparativos de dosis de níquel administrada en alimentos o agua, el 26% de la dosis administrada en agua se eliminó en la orina y el 76% en las heces en el cuarto días después de la administración (ATSDR 1997). Por el contrario el 2% de la dosis de níquel administrada en los alimentos se eliminó en la orina y el 102% en las heces durante el mismo periodo de tiempo. El níquel también se puede eliminar a través del cabello, el sudor, la leche y la piel.

#### Exposición por Inhalación

Luego de una exposición por inhalación, el níquel tiende a acumularse en los pulmones y la absorción del tracto respiratorio depende de la solubilidad del compuesto de níquel. La exposición ocupacional origina mayores cargas de níquel en los pulmones que en la población en general. Las personas sensibles al níquel presentan niveles de níquel similares en sangre, orina y cabello en relación con las personas no sensibles. El níquel inhalado se excreta a través de la orina. Estudios realizados en personas que trabajan con níquel muestran que la excreción del níquel en la orina aumenta al final del turno y también al final de la semana de trabajo, lo que indica que una fracción se elimina rápidamente y una segunda fracción se elimina lentamente. En personas no expuestas de manera ocupacional, las concentraciones de níquel tienden a ser más altas en los pulmones, la tiroides y las glándulas adrenales, los riñones, el corazón y el hígado.

### Exposición Dérmica

No se encontraron estudios sobre la excreción del níquel en seres humanos o animales después de una exposición dérmica al níquel.

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

Se reportaron efectos gastrointestinales posteriores a la ingestión agua proveniente de una fuente que contenía sulfato de níquel y cloruro de níquel por parte de trabajadores (ATSDR 1997). Las dosis de exposición variaron entre 7.1 a 35.7 mg/kg y los síntomas incluyen náuseas, dolor abdominal, vómitos y diarrea; también se observaron efectos neurológicos en los trabajadores afectados. El asma se puede presentar en un pequeño número de personas sensibilizadas, sin embargo también se demostró que la exposición oral continuada al níquel desensibiliza a algunas personas y evita la sensibilización en otros casos (ATSDR 1997). Según estudios realizados con animales, se recomienda una dosis alimenticia mínima de níquel en la dieta de 50 µg/kg (ATSDR 1997). La ingesta alimenticia promedio de níquel para las poblaciones de los Estados Unidos es de aproximadamente 150 a 168 µg/día (personas de 70 kg), de manera que no se espera que la deficiencia de níquel afecte a la población en general (ATSDR 1997).

#### Exposición por Inhalación

Los únicos datos disponibles sobre la exposición por inhalación crónica de níquel en seres humanos se limita a datos ocupacionales. Una de las limitaciones asociadas con los datos epidemiológicos disponibles es que los trabajadores se expusieron a diversas formas diferentes de níquel al igual que a otros metales y gases irritantes al mismo tiempo, de manera que con frecuencia los efectos observados no se pueden atribuir a un tipo particular de níquel y en algunos casos al níquel en general, si también se utilizan otros metales en los procesos de refinado, minado o fundición (ATSDR 1997). Otros factores relacionados con el estilo de vida como el tabaquismo, que afecta los resultados de una enfermedad, no siempre están disponibles, lo que limita las conclusiones que se puedan extraer. Los efectos respiratorios encontrados en las personas que trabajaban con níquel incluyeron bronquitis crónica, enfisema y reducción de la capacidad vital, estos trabajadores también se expusieron a otros metales, de manera que no se puede concluir que el níquel sea el único agente causante de los efectos observados. También se ha documentado la ocurrencia de asma a partir de una irritación primaria, como resultado de la sensibilización dérmica entre las personas que trabajaban con níquel. Los trabajadores de la fundición de níquel con concentraciones elevadas del mismo en la orina también mostraron un aumento significativo en los niveles de  $\beta_2$ -microglobulina urinaria, lo cual es indicativo de disfunción tubular en los riñones (ATSDR 1997).

### Exposición Dérmica

La dermatitis causada por níquel es el efecto más prevalente de níquel y ocurre en personas sensibles al mismo (ATSDR 1997). La sensibilización de níquel se origina a raíz del contacto extenso con materiales que lo contienen tales como joyas, monedas, correctores dentales, acero inoxidable, etc. El contacto causado por la exposición ocupacional también puede producir dermatitis. Una vez que una persona se convierte sensible al níquel, la siguiente exposición (mediante inhalación, ingesta o contacto dérmico) inclusive a niveles bajos pudiera causar reacción. Las poblaciones que son inusualmente susceptibles al níquel son aquellas que ya son sensibles debido al contacto prolongado y las siguientes exposiciones podrían originar una reacción alérgica. Las mujeres tienden a ser más sensibles al níquel que los hombres y se relaciona con el hecho de que ellas por lo general utilizan más joyería de metal que los hombres; se requiere el desarrollo de estudios más detallados con el fin de determinar si en realidad existe una diferencia de género en cuanto a la sensibilidad al níquel se refiere. También es probable que las personas con disfunción renal sean más susceptibles debido a que la ruta principal de eliminación del níquel es la orina.

### Dosis Referencial para la Exposición Oral Crónica (DR)

*Health Canada* desarrolló un valor de 0.0013 mg/kg/día para la ingesta diaria tolerable de cloruro de níquel (*Health Canada* 2009). No se dispone del informe de soporte.

La DR para sales solubles de níquel es 2E-2 mg/kg/día (los efectos críticos incluyen la disminución del peso corporal y el peso de los órganos) (USEPA 2006).

La Organización Mundial de la Salud dedujo una ingesta diaria tolerable (IDT) de 12 µg/kg del peso corporal para el níquel (OMS 2005, 2008). Esta IDT se dedujo a partir de un LOAEL, que a su vez se determinó a partir de un estudio en donde pacientes en ayunas con el estómago vacío experimentaron una provocación oral. El cálculo de LOAEL supone la exposición total al agua potable, es aquí importante mencionar el hecho de que la absorción en el agua potable con el estómago vacío es 10 a 40 veces más alta que la absorción en los alimentos (OMS 2008), debido a que la presencia de agua o alimentos en el estómago normalmente reduciría significativamente dicha absorción y en consecuencia la OMS no aplicó ningún factor de seguridad en la deducción del IDT ya que el LOAEL se dedujo de una población humana altamente sensible.

### Concentración Referencial para la Exposición por Inhalación Crónica (CR)

*Health Canada* (2009) publicó una CR por inhalación de 0.000018 mg/m<sup>3</sup> para el níquel metálico.

No se dispone de una CR para sales solubles de níquel (USEPA 2006).

### Efectos Cancerígenos

*Health Canada* clasificó al níquel metálico en el grupo IV (no clasificable como cancerígeno para los seres humanos) y al níquel soluble en el grupo 1 (cancerígeno para los seres humanos) (*Health Canada* 1994).

USEPA no ha evaluado la carcinogenicidad de las sales solubles de níquel.

El polvo de las fundiciones de níquel se clasifica en el grupo A, es decir cancerígeno para los seres humanos según datos sobre seres humanos los cuales indican que la exposición al polvo de fundiciones de níquel causó tumores pulmonares y nasales en trabajadores de fundiciones incluidos en varios estudios epidemiológicos y también datos sobre animales que indican la producción de carcinomas en ratas por inhalación e inyección. El níquel administrado en forma de carbonilo de níquel se fija al ADN y se clasifica en el grupo B2, es decir probable cancerígeno para los seres humanos según la observación de carcinomas pulmonares y tumores malignos en ratas a las que se administró carbonilo de níquel por inhalación e inyección intravenosa, respectivamente. El subsulfuro de níquel se encuentra en el grupo A, es decir cancerígeno para los seres humanos tomando como base el aumento de los riesgos de desarrollar cáncer pulmonar y nasal en seres humanos expuestos al polvo de fundiciones de níquel, la mayor parte del cual se cree que es subsulfuro de níquel, el aumento de las incidencias de tumores en animales mediante distintas rutas de administración en varias especies de animales y cepas y los resultados positivos en ensayos sobre genotoxicidad.

### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone de un factor de pendiente oral para ningún compuesto de níquel (USEPA 2006).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

*Health Canada* desarrolló un factor de pendiente de inhalación de  $5.5 \text{ (mg/kg/día)}^{-1}$  para el níquel soluble basado en el aumento en la incidencia de cáncer pulmonar en trabajadores expuestos en forma ocupacional (cohorte de Kristiansand 1990, según se cita en *Health Canada* 2003)

No se dispone de un factor de pendiente de inhalación para sales solubles de níquel (USEPA 2006). Sin embargo el riesgo unitario por inhalación para el polvo de fundiciones de níquel corresponde a  $2.4\text{E-}4$  per  $(\mu\text{g}/\text{m}^3)$  y para el subsulfuro de níquel es  $4.8\text{E-}4$  per  $(\mu\text{g}/\text{m}^3)$ . Ambos riesgos unitarios consideran estudios epidemiológicos de cáncer pulmonar y datos sobre carcinomas en animales.

La Organización Mundial de la Salud (OMS, 2000) derivó un riesgo unitario por inhalación basado en un estudio de poblaciones humanas expuestas de manera ocupacional susceptibles al cáncer de pulmón y no se pudo recomendar un nivel seguro para los compuestos de níquel asumiendo una respuesta lineal de la dosis. Según la información sobre la exposición y el riesgo estimado en poblaciones industriales, la OMS determinó un riesgo incremental de  $3.8 \times 10^{-4}$  para una concentración de níquel de  $1 \mu\text{g}/\text{m}^3$  en el aire (OMS 2000).

### Resumen

|                                |                                    |                  |             |
|--------------------------------|------------------------------------|------------------|-------------|
| IDT oral                       | 12 mg/kg/día                       | provocación oral | OMS 2008    |
| CR por inhalación              | no disponible                      |                  | US EPA 2004 |

## **Selenio**

### **Farmacocinética**

#### Exposición Oral

Estudios con seres humanos y animales revelan que el selenio en forma de selenita, seleniato y selenometionina se absorbe al ingerirlo a través del tracto gastrointestinal en más del 80% de la dosis administrada (ATSDR 2003). Posterior a la absorción el selenio se acumula en diversos sistemas orgánicos, encontrándose las concentraciones más altas en el hígado y los riñones, aunque los niveles de concentración en los tejidos no se correlacionan con los niveles de los efectos (ATSDR 2003). El selenio es un micronutriente esencial en seres humanos, es un componente de la sangre, el cabello y las uñas y se ha encontrado en la leche humana; se conoce también que se transfiere a través de la placenta. El exceso de selenio ingerido en forma de selenita y seleniato se metaboliza en compuestos metilados y excretados. Su eliminación ocurre a través de la orina y las heces en seres humanos y animales y la distribución entre las dos rutas varía según el nivel de exposición y el tiempo transcurrido después de la exposición (ATSDR 2003). La forma del selenio excretado depende de la forma en la que se ingirió y en el caso de exposición aguda a concentraciones tóxicas de selenio o sus compuestos, se excretan cantidades significativas mediante la exhalación de aire o el sudor en menor proporción.

#### Exposición por Inhalación

No se han realizado estudios cuantitativos con el fin de calcular la tasa de absorción del selenio elemental o de sus compuestos en seres humanos, aunque estudios ocupacionales demuestran que estas formas se absorben (ATSDR 2003). En estudios con perros y ratas se reporta que la absorción del selenio después de una exposición por inhalación es extensa, sin embargo no se dispone de estudios sobre dicha distribución en seres humanos; aunque un estudio con perros encontró absorción del selenio después de exposición a ácido selenioso y selenio elemental en forma de aerosol en el hígado, los riñones, el bazo y los pulmones (ATSDR 2003). La excreción de selenio después de una exposición por inhalación en seres humanos se realiza en el aire exhalado.

#### Exposición Dérmica

En un estudio sobre la absorción dérmica del selenio en forma de selenometionina en seres humanos no se detectó absorción transdérmica, aunque con ratones y el mismo compuesto si se encontró evidencia de absorción transdérmica (ATSDR 2003), en este caso los lugares de aplicación no se ocluyeron y la absorción después de la ingestión es posible. A pesar de que la absorción de los sulfuros de selenio no se conoce de manera profunda, se cree que los disulfuros de selenio no se absorben a través de piel

intacta. La distribución de selenio después de una exposición dérmica no se ha descrito en seres humanos, pero se ha demostrado que ocurre en el hígado y la piel de ratones tratados con una loción tópica contentiva de selenometionina (ATSDR 2003). No se dispone de estudios sobre la excreción del selenio en seres humanos o en animales después de una exposición dérmica.

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

La mayor parte de la información sobre la toxicidad de la exposición oral al selenio proviene de estudios con animales que utilizaron selenita, seleniato, sulfuros de selenio y compuestos de selenio orgánico. El ganado que pasta en áreas con altas concentraciones de selenio en la tierra se ha asociado a la “ceguera tambaleante” y a la enfermedad por alcalí, aunque también se pudiera deber a otros compuestos en la vegetación distintos al selenio. Se conoce de casos de envenenamiento accidentales en seres humanos con pocas fatalidades reportadas. En animales los compuestos tóxicos de selenio más agudos ingeridos por vía oral corresponden a la selenita de sodio y el seleniato de sodio (ATSDR 2003). Se ha reportado efectos respiratorios (incluyendo edemas y lesiones pulmonares) en seres humanos y animales así como taquicardia, malestar gastrointestinal (incluyendo náuseas, vómitos, diarrea y dolor abdominal), cambios hematológicos (en hombres), mejoras inmunológicas y linforeticulares y efectos neurológicos (incluyendo dolores de cabeza e irritabilidad) en seres humanos después de la ingestión de selenio (ATSDR 2003).

Estudios sobre la absorción oral encontraron NOAEL para el selenio (forma no especificada) de 1E-3 mg/kg/día en seres humanos después de una ingestión (que causó efectos en el sistema endocrino) hasta 464 mg/kg/día en ratones tratados con sulfuro de selenio y disulfuro de selenio por sonda (con efectos en el sistema respiratorio, cardiovascular, gastrointestinal, musculo-esquelético, hepático, endocrino y dérmico) (ATSDR 2003). Según estudios sobre absorción oral los LOAEL del selenio varían desde 1E-3 mg/kg/día en conejos machos posterior a una exposición por sonda con agua a selenita de sodio (causando una reducción significativa en los niveles de testosterona en suero) hasta 6700 mg/kg/día en ratas machos después de una exposición por sonda a selenio elemental (el valor del DL50).

#### Exposición por Inhalación

No se dispone de estudios sobre muertes de seres humanos después de una exposición por inhalación al selenio, aunque estudios realizados con animales revelan letalidad aguda en conejillos de indias expuestos a seleniuro de hidrógeno (ATSDR 2003). En estudios sobre exposición ocupacional en seres humanos se reporta que posterior a la exposición por inhalación al polvo de selenio o a otros componentes, que

el principal lugar de lesiones corresponde al tracto respiratorio, seguido de los efectos gastrointestinales y cardiovasculares y la irritación de la piel y los ojos (ATSDR 2003). También se describen efectos cardiovasculares (incluyendo shock), gastrointestinales (incluyendo vómitos y náuseas) en seres humanos expuestos al dióxido de selenio durante un incendio. La toxicidad en animales es similar y el tracto respiratorio es también el lugar principal de lesiones posterior a la exposición al polvo de selenio y al seleniuro de hidrógeno.

Estudios sobre la absorción por inhalación en animales de laboratorio encontraron NOAEL para el selenio elemental y el seleniuro de hidrógeno variando desde los 8 mg/m<sup>3</sup> en conejillos de indias (enfocándose en numerosos efectos sistémicos) hasta los 33 mg/m<sup>3</sup> en ratas, conejos y conejillos de indias (ATSDR 2003). Según estudios sobre absorción por inhalación, los LOAEL del selenio oscilaron entre 1 mg/m<sup>3</sup> en conejillos de indias expuestos a seleniuro de hidrógeno (causando la muerte) y los 33 mg/m<sup>3</sup> en ratas, conejillos de indias y conejos expuestos a selenio elemental (causando varios efectos sistémicos).

#### Exposición Dérmica

No se reporta sobre casos de muerte de seres humanos con exposición dérmica al selenio y a sus compuestos, aunque ratones expuestos a 714 mg/kg de sulfuro de selenio murieron en un lapso de 17 aplicaciones (estos lugares de aplicación no se ocluyeron y la ingestión no se pudo descartar (ATSDR 2003). No se dispone de estudios que muestren efectos respiratorios, cardiovasculares, gastrointestinales u otros efectos en seres humanos o animales después de la exposición dérmica al selenio o a sus compuestos, aunque ocurren efectos dérmicos (incluyendo quemaduras, erupciones y dermatitis por contacto) en seres humanos expuestos a vapores de selenio y óxido de selenio. Se reportan efectos oculares (incluyendo dolor severo e irritación ocular y conjuntival, lagrimeo y visión borrosa) en informes anteriores de seres humanos que tuvieron contacto ocular con dióxido de selenio.

#### Dosis Referencial para la Exposición Oral Crónica (DR)

La DR para el selenio y sus compuestos es 5E-3 mg/kg/día basada en un NOAEL de 0.015 mg/kg/día derivada de un estudio epidemiológico de la selenosis clínica en seres humanos (US EPA 2005). Se aplicó un factor de incertidumbre de 3 al NOAEL con el fin de representar a las personas sensibles, no se requirió un factor total de 10 debido a que se ha encontrado NOAEL similares en dos estudios con seres humanos de tamaño moderado. La confianza en el valor de la DR y en la base de datos es alta aunque la confianza en el estudio principal se considera media sobre la base de varias interacciones posibles no documentadas (por ejemplo, ingesta de fluoruro y estado proteico).

### Concentración Referencial para la Exposición por Inhalación Crónica (CR)

No se dispone de una CR por inhalación para el selenio o sus compuestos (US EPA 2005).

### Efectos Cancerígenos

US EPA clasifica al selenio y a los compuestos de selenio en el grupo D, es decir no clasificable como cancerígeno para seres humanos (US EPA 2005). La clasificación se basa en datos inadecuados con respecto a seres humanos y evidencia inadecuada de la carcinogenicidad en animales.

### Riesgo de Desarrollar Cáncer por exposición Oral

La base de datos para la exposición oral al selenio y a sus compuestos se considera inadecuada y no se ha determinado un factor de pendiente oral (US EPA 2005).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

La base de datos para la exposición por inhalación al selenio y a sus compuestos se considera inadecuada y no se ha determinado un factor de pendiente de inhalación (US EPA 2005).

## **Vanadio**

### **Toxicidad**

#### Efectos no Cancerígenos

##### Exposición Oral

La exposición oral a complejos de vanadilo ( $V^{+4}$ ) y vanadato ( $V^{+5}$ ), usualmente utilizados en estudios toxicológicos, origina una mezcla de complejos de vanadilo y vanadato en el tracto gastrointestinal (USEPA, NCEA 2000). En consecuencia, no existe actualmente una base toxicológica donde se pueda distinguir las relaciones dosis-respuesta para cada forma de compuesto de vanadio (USEPA, NCEA 2000). La exposición oral al vanadio en seres humanos no se caracteriza de forma profunda, aunque en un estudio con voluntarios se encontró que la administración de vanadio entre 0.47 y 1.3 mg/kg de vanadio (en forma de tartrato de vanadilo) en cápsulas durante 45 a 68 días causan calambres intestinales y diarrea, a pesar de que no se utilizaron controles del vehículo y de los compuestos (limitando así la calidad de los datos) (ATSDR 1992). De igual manera se observó que las ratas sufren de diarrea posterior a la recepción de una dosis de vanadio de 50 ppm (forma no especificada). En los experimentos con ratas también se demuestra la presencia de daños leves en los riñones (exhibidos como aumento de la urea en el plasma y leves cambios histológicos) después de 3 meses de exposición a metavanadato sódico (con niveles de hasta 10% de la  $DL_{50}$  oral) y un ligero aumento del peso corporal.

##### Exposición por Inhalación

En estudios ocupacionales con exposición por inhalación al vanadio se encontró irritación respiratoria menor como la principal forma de toxicidad y la formación de mucosidad, tos, respiración sibilante, dolor de pecho, goteo nasal y dolor de garganta como los efectos más comunes (y reversibles) (ATSDR 1992). En un estudio con voluntarios se encontró que 0.06 mg/m<sup>3</sup> de vanadio (en forma de pentaóxido de vanadio) ocasionó tos y formación de mucosidad de 7 a 24 horas posterior a la exposición. El sistema respiratorio es el objetivo principal de la toxicidad del vanadio después de una exposición por inhalación en animales; los monos que respiraron 2.8 mg/m<sup>3</sup> de vanadio (en forma de pentaóxido de vanadio) durante 6 horas mostraron un aumento de la resistencia pulmonar 1 día posterior a la exposición, con un aumento dramático en los leucocitos polimorfonucleares en el fluido broquioalveolar. Trabajadores expuestos en forma crónica a polvo de vanadio demostraron irritación ocular moderada.

##### Exposición Dérmica

No se dispone de estudios sobre la toxicidad del vanadio por exposición dérmica (ATSDR 1992).

### Dosis Referencial para la Exposición Oral Crónica (DR)

*Health Canada* no ha desarrollado una ingesta diaria tolerable para el vanadio (*Health Canada* 2004).

La DR para el pentóxido de vanadio ( $V_2O_5$ ) corresponde a  $9E-3$  mg/kg/día según un NOAEL de 17.85 ppm (ajustado a 0.89 mg/kg/día) (USEPA 1996). El valor se basa en un estudio oral crónico realizado con ratas, arrojando una disminución del contenido de la cistina del cabello como el efecto crítico. Se aplicó un factor de incertidumbre total de 100, con un factor de 10 para la extrapolación interespecies y un factor de 10 para proteger a las poblaciones sensibles. Se reportó que la confianza en la DR oral del pentóxido de vanadio es baja debido a la calidad del estudio, la base de datos y el valor de la DR según la escasez de datos disponibles (USEPA, 1996).

US EPA Región 9 publicó una DR de 0.00504 mg/kg-día para el vanadio, sobre la base de la DR establecida por USEPA IRIS con un ajuste debido a las diferencias en el peso molecular.

ATSDR desarrolló un nivel mínimo de riesgo oral de duración intermedia (NMR) para el vanadio (en forma de metavanadato sódico) de  $3E-3$  mg/kg/día según un nivel sin efectos adversos observados (NOAEL) de 0.3 mg/kg/día para efectos renales y respiratorios (focos hemorrágicos renales e infiltración vascular pulmonaria), encontrado en un estudio de 3 meses de duración con ratas expuestas al vanadio mediante agua potable (Domingo 1985, según se cita en ATSDR 1992). ATSDR (1992) no desarrolló un NMR oral crónico, sin embargo se puede aplicar un factor de 10 al NMR de duración intermedia con el fin de representar una duración crónica y arrojando como resultado un NMR de  $3E-4$  mg/kg/día.

La DR de la tabla MPR de USEPA Región 9 (basada en el USEPA IRIS) se utilizará en esta evaluación de riesgos ya que las otras derivaciones corresponden al vanadio (IV).

### Concentración Referencial para Exposición por Inhalación Crónica (CR)

*Health Canada* no ha desarrollado una concentración tolerable para el vanadio (*Health Canada* 1996).

Actualmente no se dispone de una CR referente al vanadio o el pentóxido de vanadio (USEPA 2004). ATSDR desarrolló un NMR para inhalación de duración aguda de  $2E-4$  mg/m<sup>3</sup> basado en un LOAEL de 0.06 mg/m<sup>3</sup>, el cual ocasionó tos e irritación respiratoria en voluntarios humanos expuestos a polvo de pentóxido de vanadio durante 8 horas (Zenz and Berg 1967, según se cita en ATDR 1992). El NMR correspondiente a inhalación de duración aguda se dedujo corrigiendo el NOAEL para exposición continua y posteriormente dividiéndolo por un factor de incertidumbre de 100 (dando cuenta de

la variabilidad de los seres humanos y el uso de un LOAEL en lugar de un NOAEL). No se identifican datos cuantitativos adecuados sobre la exposición con el fin de calcular un NMR correspondiente a inhalación intermedia o crónica.

### Efectos Cancerígenos

*Health Canada* no ha clasificado la posible carcinogenicidad de vanadio (*Health Canada* 2004) y actualmente no se dispone de la clasificación de carcinogenicidad para el vanadio o pentóxido de vanadio por parte de USEPA (USEPA 1988, 1996). Tampoco se han encontrado estudios de carcinogenicidad mediante exposiciones orales o dérmicas para compuestos de vanadio pentavalente. Se reportó clara evidencia de carcinogenicidad en un estudio con ratones machos y hembras expuestos al pentóxido de vanadio mediante inhalación y cierta evidencia de carcinogenicidad en ratones machos, pero no en ratas hembras según la presencia de neoplasmas alveolares/bronquiales (Ress 2003). Los efectos se observaron para concentraciones inhaladas que exceden ligeramente los límites de exposición ocupacional humana permisible ( $0.5 \text{ mg/m}^3$ ; Ress 2003). Estudios crónicos realizados con ratas (Dai 1994, Dai y McNiel 1994, según se cita en OMS 2001) y en ratones (Kanisawa y Schroeder 1967, según se cita en UK EGVM) expuestos a sulfato de vanadio en agua potable, no aumentaron la incidencia de tumores espontáneos en ratones o ratas, aunque causaron una reducción en el aumento de peso corporal en ratas. La Agencia Internacional para la Investigación del Cáncer (IARC 2005) clasificó al pentóxido de vanadio en el grupo 2B, es decir posiblemente cancerígeno para seres humanos.

### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone de un factor de pendiente oral para el vanadio o pentóxido de vanadio (*Health Canada* 2004 y USEPA 1988, 1996).

### Riesgo de Desarrollar Cáncer Debido a una Exposición por Inhalación

No se dispone de un factor de pendiente de inhalación para el vanadio o pentóxido de vanadio (*Health Canada* 2004 y USEPA 1988, 1996).

### **Resumen**

## **Zinc**

### **Farmacocinética**

#### Exposición Oral

La farmacocinética del zinc posterior a una exposición oral se considera bien caracterizada en seres humanos, ya que es un nutriente esencial y uno de los metales traza más abundantes en el cuerpo humano (ATSDR 2003). La absorción a través del duodeno y los intestinos se regula en forma homeostática, y en condiciones fisiológicas normales 20 a 30% del zinc ingerido se absorbe a través de difusión pasiva y un proceso por mediación de un portador. El contenido de zinc más alto corresponde a los músculos, los huesos, el tracto gastrointestinal, los riñones, el cerebro, la piel, los pulmones, el corazón y el páncreas (ATSDR 2003).

La mayor parte del zinc se excreta mediante las heces y también mediante la orina, las rutas menores corresponden a la secreción salival, la pérdida de cabello y el sudor.

#### Exposición por Inhalación

La información disponible sobre la absorción, distribución y excreción del zinc después de la exposición por inhalación en seres humanos y animales, se considera limitada, aunque estudios reportan un aumento en los niveles del zinc en la sangre y en la orina después de la exposición por inhalación (ATSDR 2003). La absorción de zinc a través de los pulmones depende del tamaño de las partículas y de la solubilidad de su compuesto y en un estudio ocupacional se reportó elevados niveles de zinc en la orina posterior a la exposición al mismo, lo cual sugiere que la orina es una ruta de excreción principal.

#### Exposición Dérmica

La información disponible sobre la absorción, distribución y excreción del zinc después de la exposición dérmica en seres humanos y animales, se considera limitada, aunque estudios reportan un aumento en los niveles del zinc en la sangre y en la orina después de la exposición a la piel (ATSDR 2003). No se encontraron estudios sobre la excreción del zinc después de la exposición dérmica en seres humanos o animales (ATSDR 2003).

## **Toxicidad**

### Efectos no Cancerígenos

#### Exposición Oral

Los efectos de la exposición oral del zinc en seres humanos incluyen efectos gastronómicos, efectos hematológicos, daños inmunológicos y respuestas inflamatorias después de dosis altas, y efectos neurológicos después de la ingesta de zinc metálico (causando letargo, mareos, tambaleos y dificultad para escribir) (ATSDR 2003).

#### Exposición por Inhalación

Los efectos de la exposición por inhalación del zinc en seres humanos incluyen: fiebre por humo de metales (de óxidos de zinc), daños a las membranas mucosas y disnea, tos, dolor pleurítico del pecho, irritación del tracto respiratorio (cloruro de zinc), náuseas (óxido de zinc y vapores de cloruro) y varios efectos inmunológicos (óxido de zinc) (ATSDR 2003).

#### Exposición Dérmica

Los efectos de la exposición dérmica al zinc en seres humanos incluyen: anemia y disminución del número de plaquetas (después de la exposición a soluciones de cloruro de zinc), irritación cutánea general después de la exposición a cloruro de zinc y daño ocular después de la exposición ocular directa a una pasta que contiene 30% de cloruro de zinc (ATSDR 2003).

#### Dosis Referencial para la Exposición Oral Crónica (DR)

*Health Canada* publicó una ingesta diaria tolerable de 0.5 mg/kg/día para el zinc (*Health Canada* 2009).

USEPA desarrolló una DR para el zinc de  $3 \times 10^{-1}$  mg/kg/día tomando como base un estudio sobre suplementos alimenticios para seres humanos el cual encontró una reducción del 47% del superóxido dismutasa de los eritrocitos y enzimas de la sangre en mujeres adultas después de una exposición de 10 semanas (USEPA 2006). No se determinó un NOAEL aunque el LOAEL correspondió a 59.72 mg/día (convertidos en 1.0 mg/kg/día, sobre la base de un peso corporal de 60 kg para las mujeres). Se aplicó un factor de incertidumbre de 3 para un LOAEL derivado de un estudio sobre exposición de duración moderada (el cual utilizó una sub-población sensible) y el hecho de que el zinc es un nutriente esencial (USEPA 2006). Se reportó que la confianza en la DR es media debido al estudio, la base de datos y el valor de la DR.

### Concentración Referencial para Exposición por Inhalación Crónica (CR)

Actualmente no se dispone de una CR o concentración tolerable para el zinc (USEPA 2006 y *Health Canada* 2009).

### Efectos Cancerígenos

*Health Canada* no ha evaluado la carcinogenicidad del zinc (*Health Canada*, 1996). USEPA lo clasifica en el grupo D, es decir no clasificable como cancerígeno para los seres humanos, según la evidencia inadecuada con respecto a los seres humanos y los animales (USEPA 2006).

### Riesgo de Desarrollar Cáncer por Exposición Oral

No se dispone del factor de pendiente oral para el zinc y (*Health Canada* 2009 USEPA 2006).

### Riesgo de Desarrollar Cáncer Debido a la Exposición por Inhalación

No se dispone del factor de pendiente de inhalación para el zinc (*Health Canada* 2009 y USEPA 2006).

## **1 RESUMEN**

En este apéndice se resume los datos, métodos y fuentes de material bibliográfico utilizadas con el fin de obtener parámetros para el modelo de la cadena alimenticia de la vida silvestre. Los parámetros requeridos incluyen:

- concentraciones de CIP en elementos de la dieta; y
- parámetros de exposición específicos del receptor, incluyendo peso corporal, composición de la dieta, tasas de ingesta de alimentos, agua y suelos, y tamaño del ámbito de hogar.

Las hojas de cálculo del modelo de la cadena alimenticia en Excel<sup>TM</sup> se presentan en el Anexo XIX, Apéndice I. Los valores y fuentes de los parámetros se presentan en las hojas de cálculo.

## 2 ESTRUCTURA DEL MODELO DE LA CADENA ALIMENTICIA

Para cada combinación de CIP y receptor se calculó una dosis diaria total (mg/kg-día) según la siguiente ecuación:

$$Dosis = \frac{TIA \cdot C_{dieta} + TIA \cdot C_{agua} + TIS \cdot C_{suelo}}{PC}$$

donde TIA corresponde a la tasa de ingesta de alimentos (kg<sub>alimento-húmedo</sub>/día), WIR a la tasa de ingesta de agua (L<sub>agua</sub>/día), SIR a la tasa de ingesta de suelos (kg<sub>suelo-seco</sub>/día), Ci a la concentración de CIP en la dieta (mg<sub>CIP</sub>/kg<sub>alimentos-húmedo</sub>), agua (mg<sub>COPC</sub>/L) o suelo (mg<sub>CIP</sub>/kg<sub>suelo-seco</sub>), y PC al peso corporal (kg) del receptor. C<sub>dieta</sub>; se calculó a partir de las concentraciones de CIP medidas o estimadas para cada elemento de la dieta, ponderada por la fracción de cada elemento en la dieta del receptor. Se supuso que todos los receptores obtuvieron 100% de alimentos, agua y suelo consumidos dentro del área de estudio principal (es decir el tamaño del ámbito de hogar de todas las especies de receptores resultó menor que el área de estudio principal). Se asumió también que se dispuso del total de los CIP en todos los medios al 100% (es decir no se efectuó ningún ajuste para la posible biodisponibilidad limitada de los CIP en uno o más medios); correspondiendo a un supuesto conservador el cual se utiliza para la evaluación a nivel de análisis, debido a que muchos metales tienen una biodisponibilidad limitada en relación con las sales de metales solubles que normalmente se aplican en estudios toxicológicos como base para los valores de referencia de la toxicidad.

### 2.1 CONCENTRACIONES DE CIP EN LOS ELEMENTOS DE LA DIETA

A menos que se especifique lo contrario, todas las concentraciones de CIP en los tejidos (vegetación, cultivos, peces, invertebrados) se reportaron como concentraciones en peso húmedo, o convertidas a concentraciones en peso húmedo antes del modelado. Las concentraciones de CIP de suelo se expresaron como concentraciones de peso seco con el fin de evitar confundir la influencia de alta variabilidad en el contenido de humedad del suelo. Tal como se indicó anteriormente la tasa de ingesta de suelo por lo tanto se expresó en términos de peso seco. Las concentraciones de CIP de línea base y del caso de impacto en el suelo, agua, invertebrados terrestres, hojas, frutas y peces utilizadas en el modelo de la cadena alimenticia se incluyen en el Anexo XIX, Apéndice I y las concentraciones de CIP en insectívoros y mamíferos

herbívoros pequeños así como en mamíferos herbívoros grandes se indican a continuación.

### 2.1.1 Mamíferos Pequeños

Las concentraciones de CIP en mamíferos pequeños (como presas de jaguares y águilas crestadas) se estimaron a partir de las concentraciones de CIP en el suelo o en la dieta utilizando las ecuaciones que se describen más adelante (Tabla 1). El resumen de las estadísticas para las concentraciones de CIP en el suelo (estimados de exposición del límite superior y de tendencia central) se presenta en el Anexo XIX, Apéndice C y las concentraciones de CIP en los tejidos de la dieta de mamíferos pequeños (es decir, gusanos) se estimaron tal como se describe en el Anexo XIX, Apéndice C. Cuando se requirió la conversión de las concentraciones de tejido de peso seco a peso húmedo, se utilizó un contenido de humedad promedio específico para el área de 76%

### 2.1.2 Mamíferos Herbívoros Pequeños

Las concentraciones de CIP en mamíferos pequeños herbívoros se estimaron a partir de la dosis diaria de CIP para el mono araña (estimada a través del modelo de la cadena alimenticia, Anexo XIX, Apéndice I) utilizando factores de transferencia de bioacumulación (Baes 1984). Los únicos factores de transferencia de bioacumulación disponibles en el material bibliográfico consultado con el fin de representar a las especies herbívoras se infirieron a partir de los datos del ganado, para los fines de la evaluación estos factores de transferencia se asumieron con el objeto de representar al mono araña y a otros herbívoros pequeños consumidos por el jaguar y el águila crestada. A continuación se presenta un resumen de las ecuaciones utilizadas para las estimaciones (Tabla 2). Cuando se requirió la conversión de las concentraciones tisulares de peso seco a peso húmedo se utilizó un contenido de humedad de 68% (USEPA 1993)

**Tabla 2                      Resumen de Modelos de Bioacumulación para Mamíferos Pequeños Herbívoros**

| COPC      | Modelo de Bioacumulación                              |           |

### 2.1.3 Mamíferos Herbívoros Grandes

Las concentraciones de CIP en mamíferos herbívoros grandes se estimaron a partir de la dosis diaria de CIP para el tapir de Baird (estimada a través del modelo de la cadena

alimenticia Anexo XIX, Apéndice I) utilizando para ello factores de transferencia de bioacumulación (Baes 1984). Los únicos factores de transferencia de bioacumulación disponibles en el material bibliográfico consultado con el fin de representar a las especies herbívoras se infirieron a partir de los datos del ganado; para los fines de esta evaluación los factores de transferencia se asumieron para representar al tapir de Baird y a otros herbívoros grandes consumidos por el jaguar y el águila crestada. A continuación se resumen las ecuaciones utilizadas para las estimaciones (Tabla 3). Cuando se requirió la conversión de las concentraciones tisulares de peso seco a peso húmedo se utilizó un contenido de humedad de 68% (USEPA 1993).

**Tabla 3                    Resumen de Modelos de Bioacumulación para Mamíferos Herbívoros Grandes**

## 2.2                    PARAMETRIZACIÓN DE RECEPTORES

Los valores de cada parámetro se resumen en las hojas de cálculo del modelo de la cadena alimenticia específico para cada receptor (Anexo XIX, Apéndice I). A continuación se incluye los detalles con respecto a la fuente y la derivación de cada valor de parámetro de cada receptor.

## 2.2.1 Peso Corporal

Los valores de peso corporal (PC, kg) se obtuvieron de las fuentes a las que se hace referencia en la Tabla 4.

**Tabla 4 Pesos Corporales Utilizados para los Receptores**

| Receptor de Vida Silvestre | Peso Corporal [kg] | Referencia                                                      |
|----------------------------|--------------------|-----------------------------------------------------------------|
| <b>Mamíferos</b>           |                    |                                                                 |
| jaguar                     | 80.6               | Cascelli de Azevedo y Murray (2007) (media de machos y hembras) |
| tapir de Baird             | 250                | Foerster (2000) (estimado medio utilizado)                      |
| mono araña                 | 5.48               | Clark (1944) (media de 19 monos araña adultos)                  |
| armadillo                  | 6.0                | Frappell (1998)                                                 |
| <b>Aves</b>                |                    |                                                                 |
| águila crestada            | 2.9                | (hembra en cautiverio) Kiff et Al., 1989                        |
| martín pescador grande     | 0.32               | Wildbirds Unlimited (2009)                                      |
| Loro cabeza azul           | 0.29               | Gilardi y Munn (1988)                                           |
| zorzalito de Swainson      | 0.03               | Dunning (1984)                                                  |

Nota: kg = kilogramo.

## 2.2.2 Tasa de Ingesta de Alimentos

Las tasas de ingesta de alimentos (TIA) se expresan en kg alimentos/día peso húmedo (ph) y se obtuvieron de las fuentes a las que se hace referencia en la Tabla 5.

**Tabla 5 Tasas de Ingesta de Alimentos Utilizadas para los Receptores**

| Receptor de Vida Silvestre | FIR<br>[kg <sup>dieta-húmedo</sup> /día] | Referencia                                                                              |
|----------------------------|------------------------------------------|-----------------------------------------------------------------------------------------|
| <b>Mamíferos</b>           |                                          |                                                                                         |
| jaguar                     | 1.4                                      | Emmons (1987) (basado en un jaguar en cautiverio)                                       |
| tapir de Baird             | 20.7                                     | USEPA 1993 (TIA calculada para todos los mamíferos)<br>$TIA = 0.0687 \times PC^{0.822}$ |
| mono araña                 | 1.11                                     | USEPA 1993 (TIA calculada para todos los mamíferos)<br>$TIA = 0.0687 \times PC^{0.822}$ |
| armadillo                  | 1.25                                     | USEPA 1993 (TIA calculada para todos los mamíferos)<br>$TIA = 0.0687 \times PC^{0.822}$ |
| <b>Aves</b>                |                                          |                                                                                         |
| águila crestada            | 0.195                                    | USEPA (1993) (TIA calculada para todas las aves)<br>$TIA = 0.0582 \times PC^{0.651}$    |
| martín pescador grande     | 0.16                                     | Sample y Suter 1994 (martín pescador norteno, ajustado para PC)                         |
| loro cabeza azul           | 0.109                                    | USEPA (1993) (TIA calculada para todas las aves)<br>$TIA = 0.0582 \times PC^{0.651}$    |
| zorzalito de Swainson      | 0.025                                    | USEPA (1993) (TIA calculada para todas las aves)<br>$TIA = 0.0582 \times PC^{0.651}$    |

Notas: Las TIA calculadas se convirtieron a una concentración ph dividiendo la tasa de ingesta de alimentos por 1-MC, PC = peso corporal, TIA = tasa de ingesta de alimentos, CH = contenido de humedad, ph = peso húmedo.

### 2.2.3 Tasa de Ingesta de Agua

Las tasas de ingesta de agua (TIA) se expresan en L/día y se obtuvieron de las fuentes a las que se hace referencia en la Tabla 6.

**Tabla 6 Tasas de Ingesta de Agua Utilizadas para los Receptores**

| Receptor de Vida Silvestre | TIA [L/día] | Referencia                                                                           |
|----------------------------|-------------|--------------------------------------------------------------------------------------|
| <b>Mamíferos</b>           |             |                                                                                      |
| jaguar                     | 5.14        | USEPA 1993 (TIA calculada para todos los mamíferos)<br>$TIA = 0.099 \times PC^{0.9}$ |
| tapir de Baird             | 14.25       | USEPA 1993 (TIA calculada para todos los mamíferos)<br>$TIA = 0.099 \times PC^{0.9}$ |
| mono araña                 | 0.46        | USEPA 1993 (TIA calculada para todos los mamíferos)<br>$TIA = 0.099 \times PC^{0.9}$ |
| armadillo                  | 0.50        | USEPA 1993 (TIA calculada para todos los mamíferos)<br>$TIA = 0.099 \times PC^{0.9}$ |
| <b>Aves</b>                |             |                                                                                      |
| águila crestada            | 0.122       | USEPA 1993 (TIA calculada para todas las aves)<br>$TIA = 0.059 \times PC^{0.67}$     |
| martín pescador grande     | 0.034       | Sample y Suter (1994) (martín pescador norteno, ajustado para PC)                    |
| loro cabeza azul           | 0.026       | USEPA 1993 (TIA calculada para todas las aves)<br>$TIA = 0.059 \times PC^{0.67}$     |
| zorzalito de Swainson      | 0.006       | USEPA 1993 (TIA calculada para todas las aves)<br>$TIA = 0.059 \times PC^{0.67}$     |

Notas: PC - peso corporal, TIA - Tasa de ingesta de alimentos, CH - contenido de humedad, ph - peso húmedo

## 2.2.4 Tasa de Ingesta de Suelo

Las tasas de ingesta de suelo (TIS) se expresan en L/día y se obtuvieron de las fuentes a las que se hace referencia en la Tabla 7. Las TIS para el jaguar y el mono araña se asumieron como cero (es decir la ingesta incidental de suelo es insignificante) según los hábitos alimenticios de estas especies.

**Tabla 7 Tasas de Ingesta de Suelo Utilizadas para los Receptores**

| <b>Receptor de Vida Silvestre</b> | <b>TIS<br/>(kg<sub>suelo-seco</sub>/día)</b> | <b>Referencia</b>                                                                                                           |
|-----------------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Mamíferos</b>                  |                                              |                                                                                                                             |
| jaguar                            | 0                                            | Emmons (1987)                                                                                                               |
| tapir de Baird                    | 0.15                                         | Beyer (1994) (2.3 por ciento de la TIA de peso seco, extraída del jabalí)                                                   |
| mono araña                        | 0                                            | White (1986)                                                                                                                |
| armadillo                         | 0.05                                         | Beyer (1994) (17% de la TIA de peso seco)                                                                                   |
| <b>Aves</b>                       |                                              |                                                                                                                             |
| águila crestada                   | 0                                            | Sample y Suter (1994) (águila calva)                                                                                        |
| martín pescador grande            | 0                                            | Sample y Suter (1994) (martín pescador norteno)                                                                             |
| loro cabeza azul                  | 0.0026                                       | Se asume como el 10% de la TIA debido a las marcas dejadas por las aves en las paredes de arcilla (Burger y Gochfeld, 2003) |
| zorzalito de Swainson             | 0.0001                                       | Sample y Suter (1994) (petirrojo americano)                                                                                 |

Nota: TIS - tasa de ingesta de suelo

### 2.2.5 Preferencias Dietarias

Las preferencias dietarias para los receptores en este estudio tuvieron por finalidad representar a las comunidades de alimentación genéricas (por ejemplo insectívoros, herbívoros, carnívoros) en contraposición con una evaluación de la conducta de alimentación específica del área de cualquier especie individual. Las preferencias dietarias para los receptores seleccionados se muestran en la Tabla 8.

**Tabla 8 Preferencias Dietarias Utilizadas para los Receptores**

| <b>Receptor de Vida Silvestre</b> | <b>Dieta [porcentaje]</b>                                                                                          | <b>Referencia</b>                                                                                                                                                                       |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Mamíferos</b>                  |                                                                                                                    |                                                                                                                                                                                         |
| jaguar                            | 30% de mamíferos herbívoros grandes, 30% de mamíferos herbívoros pequeños, 30% de mamíferos pequeños, 10% de peces | estimado según Emmons (1987)                                                                                                                                                            |
| tapir de Baird                    | 100% de hojas                                                                                                      | Tobler (2002)                                                                                                                                                                           |
| mono araña                        | 80% de fruta, 20% de hojas                                                                                         | White (1986)                                                                                                                                                                            |

Los zorzalitos de Swainson se alimentan también de algunas frutas en el invierno aunque se asumió en forma conservadora, que comían únicamente invertebrados terrestres |

### 2.2.6 Rango de Hábitat

Se utilizó datos de ámbito de hábitat con el fin de estimar el porcentaje global de tiempo que un receptor pasa dentro del área de estudio, el tamaño del área de estudio principal se estimó en 41,351 hectáreas (Figura 1-2), y todos los receptores tienen un rango de hábitat más pequeño que el área de estudio principal y en consecuencia se

## Parámetros de Exposición para la Evaluación de Riesgos a la Vida Silvestre

espera que obtengan 100% de su dieta dentro del área de estudio principal. El jaguar es la especie faunística con el rango de hogar más grande, el cual es aproximadamente 60 km<sup>2</sup> en el hábitat del bosque tropical para los machos y 40 km<sup>2</sup> para las hembras (Silver 2004, Cascelli de Azevedo y Murray 2007). De esta manera, el área de estudio principal se considera suficientemente grande como para contener varios rangos de hogar del jaguar). En la Tabla 9 se presenta los rangos de hábitat para los receptores de vida silvestre.

**Tabla 9 Rangos de Hábitat Utilizados para los Receptores**

| Receptor de Vida Silvestre | Rango de Hábitat [ha] | Referencia                                                                                                 |

## **1 GENERALIDADES**

Este apéndice presenta un resumen de los métodos y fuentes de datos utilizados para obtener los valores de referencia de toxicidad (VRT) aplicables a la evaluación del riesgo para la fauna silvestre. Los VRT se utilizan como umbrales de efectos para la evaluación de las tasas estimadas de consumo de contaminantes de interés potencial (CIP) por parte de los receptores. Las Tablas 1 y 2 presentan un resumen de los VRT obtenidos.

Tabla 1 Datos de Toxicidad Utilizados para Calcular los Valores de Referencia de Toxicidad en Mamíferos

| Parámetro      | VRT Inferiores | VRT Superiores | Detalles del Estudio de Toxicidad                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Metales</b> |                |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Aluminio (Al)  | 1.93           | 19.3           | No existían niveles de ecológicos de evaluación del suelo (Eco-SSL) para los efectos del aluminio en las especies de mamíferos de la fauna silvestre. La Agencia de Protección Ambiental de los Estados Unidos (USEPA 2003) reconoce que los parámetros de evaluación del suelo que se utilizan comúnmente se basan en pruebas de toxicidad de laboratorio en las que se añade una solución de aluminio a los suelos de prueba, los cuales no son relevantes para las muestras de suelo de campo. Por tal motivo, los valores de referencia de toxicidad (VRT) utilizados en la Evaluación del Riesgo para la Ecología (ERE) son sumamente conservadores, y se debe tener cuidado al interpretar los casos en los que se exceden los VRT. Sample et al. (1996) obtuvieron una serie de VRT a partir de un estudio de exposición al aluminio a través del agua para beber en tres generaciones de ratones (Ondreicka et al. 1966). Se registró una concentración de efecto negativo mínimo observado (LOAEC) de 19.3 mg/kg-día para los efectos en la reproducción (es decir, número de camadas, número de crías y crecimiento) en ratones de laboratorio expuestos a 19.3 mg/kg-día de aluminio (cloruro de aluminio). Se aplicó un factor de extrapolación de 10 a la LOAEC a fin de obtener una concentración de efecto negativo no observado (NOAEC) de 1.93 mg/kg-día. Se consideró que la exposición era crónica porque se extendió más de un año y durante una etapa crítica completa (es decir, durante la reproducción). |
| Antimonio (Sb) | 0.059          | 0.59           | Había un Eco-SSL de la USEPA disponible (2005a). Se calculó una media geométrica de 13.3 mg/kg bw/día Sb con respecto a los valores de la NOAEC para el crecimiento y la reproducción. Sin embargo, debido a que este valor era superior a la LOAEC determinada más baja para los efectos en la reproducción, crecimiento o supervivencia, el VRT inferior fue fijado en 0.059 mg/kg-día Sb, lo cual corresponde a la NOAEC determinada más alta por debajo de la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. El valor del NOAEC se derivó del estudio con ratas realizado por Rossi et al. (1987) en el que se administró antimonio a las ratas hembras en el agua durante 31 días y se observó un efecto en el peso de las crías. El LOAEC obtenido en este estudio fue utilizado como el VRT (0.59 mg/kg-día Sb).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Arsénico (As)  | 1.04           | 1.66           | La media geométrica de los valores del NOAEL para el crecimiento y la reproducción basada en diversos estudios con mamíferos de laboratorio estándar fue calculada en 2.47 mg/kg-día (U.S. EPA 2005b). Sin embargo, debido a que este valor fue superior al LOAEL determinado más bajo para los resultados de reproducción, crecimiento o supervivencia, se estableció un VRT de 1.04 mg/kg-día, el cual corresponde al NOAEL determinado más alto por debajo del LOAEL determinado más bajo para la reproducción, crecimiento o supervivencia (Neiger y Osweiler 1989; citado en US EPA 2005b). Los VRT se derivaron de un estudio de alimentación de 8 meses en perros jóvenes (Canis familiares) y el LOAEL se basó en los efectos sobre el crecimiento.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Bario (Ba)     | 51.8           | 121            | Había un Eco-SSL de la USEPA disponible (2005b). Se revisó diez estudios con especies de mamíferos (y 27 puntos finales de efectos). Se calculó una media geométrica de 51.8 mg/kg-día Ba con respecto a los valores de la NOAEC para los efectos en el crecimiento y la reproducción. Este valor fue inferior a la LOAEC determinada más baja para reproducción, crecimiento o supervivencia; por consiguiente, el VRT inferior fue fijado en 51.8 mg/kg-día Ba. El valor de la LOAEC determinada más baja fue 121 mg/kg-día Ba (Dietz et al. 1992, citado en USEPA 2005b).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Cadmio (Cd)    | 0.77           | 7.7            | Había un Eco-SSL de la USEPA disponible (2005c). Se calculó una media geométrica de de 1.86 mg/kg-día Cd con respecto a los valores de la NOAEC para la reproducción y el crecimiento. Sin embargo, este valor era superior a la LOAC determinada más baja para la reproducción, el crecimiento o la mortalidad; por lo tanto, el VRT inferior tuvo un valor similar al de la NOAEC determinada más alta por debajo de la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia (0.77 mg/kg-día Cd; USEPA 2005c). La LOAEC correspondiente fue 7.7 mg/kg-día Cd.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Cromo (Cr)     | 2.4            | 2.82           | En el caso del cromo trivalente, la media geométrica de los valores del NOAEL para el crecimiento y la reproducción basada en múltiples estudios con mamíferos de laboratorio fue calculada en 2.40 mg/kg-día (U.S. EPA 2008a). Dicho valor fue utilizado como el VRT inferior. No existía un LOAEL determinado para el cromo trivalente; por lo tanto, el valor del LOAEL más bajo para el crecimiento, la reproducción y la supervivencia por encima del NOAEL establecido por la US EPA (US EPA 2008a) fue utilizado como VRT (2.82 mg/kg-día). Este LOAEL se basa en un estudio realizado por Mercado y Bibby (1973) en el que se expuso a ratas jóvenes a cromo III a través del agua para beber durante un periodo de 50 días. El LOAEL se basa en una reducción de la supervivencia.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Cobalto (Co)   | 7.33           | 10.9           | Había un Eco-SSL de la USEPA disponible (2005d). Se calculó una media geométrica de 7.33 mg/kg-día Co con respecto a los valores del NOAEL para el crecimiento y la reproducción. Este valor es inferior a la LOAEC determinada más baja para los puntos finales de reproducción, crecimiento o supervivencia. Por lo tanto, el VRT inferior tuvo el mismo valor que la media geométrica de los valores de NOAEL para la reproducción y el crecimiento (7.33 mg/kg-día Co). La LOAEC determinada más baja para los puntos finales de supervivencia, reproducción y crecimiento fue 10.9 mg/kg-día Co (Domingo et al. 1985, citado en USEPA 2005d).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Tabla 1 Datos de Toxicidad Utilizados para Calcular los Valores de Referencia de Toxicidad en Mamíferos (continuación)

| Parámetro      | VRT Inferiores | VRT Superiores | Detalles del Estudio de Toxicidad                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|----------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cobre (Cu)     | 5.6            | 9.34           | Había un Eco-SSL de la USEPA disponible (2007a). Se calculó una media geométrica de 25 mg/kg-día Cu con respecto a los valores de la NOAEC para la reproducción y el crecimiento. Sin embargo, debido a que este valor fue superior a la LOAEC determinada más baja para los resultados de reproducción, crecimiento o mortalidad, el VRT fue igual a la NOAEC determinada más alta por debajo de la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. El último valor fue 5.6 mg/kg-día Cu, y fue obtenido a partir de un estudio de exposición de cerdos jóvenes al cobre ( <i>Sus scrofa</i> ) durante 4 semanas; los puntos finales sensitivos incluyeron el crecimiento y la supervivencia (Allcroft et al. 1961). La LOAEC correspondiente fue 9.34 mg/kg-día Cu.                                                                                                |
| Plomo (Pb)     | 4.7            | 8.9            | Había un Eco-SSL de la USEPA disponible (2005e). Se calculó una media geométrica de 40.7 mg/kg-día Pb con respecto a los valores del NOAEL para la reproducción y el crecimiento. Sin embargo, debido a que este valor es superior a la LOAEC determinada más baja para los resultados de reproducción, crecimiento y mortalidad, el valor del VRT fue igual al del NOAEL determinado más alto por debajo de la LOAEC determinada más baja para la reproducción, el crecimiento y la supervivencia. El valor de este último fue 4.70 mg/kg-día Pb, y se derivó de un estudio de toxicidad del plomo en ratas ( <i>Rattus norvegicus</i> ) realizado por Kimmel et al. (1980, citado en USEPA 2005e) en el que se administró plomo durante 7 semanas a través del agua para beber. Los valores de la NOAEC y la LOAEC para el crecimiento en el estudio fueron 4.70 y 8.90 mg/kg-día Pb, respectivamente. |
| Molibdeno (Mo) | 0.26           | 2.6            | No existían Eco-SSLs para los efectos del molibdeno en las especies de mamíferos de la fauna silvestre. Se registró una LOAEC (2.6 mg/kg-día) y una NOAEC (0.26 mg/kg-día) para la reproducción (incidencia de enanismo) en los ratones expuestos a molibdato a través del agua por tres generaciones (Schroeder y Mitchner 1971, citado en Sample et al. 1996). Se consideró que el grado de exposición era crónico pues se produjo durante un periodo superior a un año y en una etapa crítica (reproducción).                                                                                                                                                                                                                                                                                                                                                                                         |
| Selenio (Se)   | 0.143          | 0.215          | Se utilizó un Eco-SSL de la USEPA (2007d) para identificar el VRT. Se calculó una media geométrica de 0.437 mg/kg-día con respecto a los valores de la NOAEC para la reproducción y el crecimiento. Sin embargo, este valor era superior a la LOAEC determinada más baja para los resultados de reproducción, crecimiento o mortalidad; por lo tanto, el valor del VRT fue igual al de la NOAEC determinada más alta por debajo de la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. LA NOAEC fue obtenida a partir de un estudio (Mahan y Moxon 1984, citado en USEPA 2007d) en el que se expuso a cerdos jóvenes al selenio a través de la dieta durante un periodo de 37 días, en el que se observó una reducción en el peso corporal. El valor de la LOAEC (0.215 mg/kg-día Se) derivado de este estudio fue utilizado como el VRT superior.                    |
| Estroncio (Sr) | 263            | No disponible  | No existían Eco-SSL para los efectos del estroncio en las especies de mamíferos de la fauna silvestre. Se obtuvo un NOAEL de 263 mg/kg-día Sr a partir de un estudio en el que las ratas fueron expuestas al cloruro de estroncio a través del agua (3 niveles de dosis) durante 3 años (Skoryna 1981, citado en Sample et al. 1996). No se observó efectos negativos en ninguno de los niveles de dosis. No se pudo obtener una LOAEC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Vanadio (V)    | 4.16           | 8.31           | Había un Eco-SSL de la USEPA disponible (2005f). Se calculó una media geométrica de 5.92 mg/kg-día V con respecto a los valores de la NOAEC para el crecimiento y la reproducción. Sin embargo, debido a que esta media geométrica de la NOAEC fue superior a la LOAEC determinada más baja para el crecimiento, la reproducción o la supervivencia, el valor del VRT inferior fue igual a la NOAEC determinada más alta por debajo de la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. El valor del VRT inferior fue 4.16 mg/kg-día V y se basó en el estudio realizado por Sanchez et al. (1991) sobre la exposición de ratones ( <i>Mus musculus</i> ) al vanadio. La LOAEC fue 8.31 mg/kg-día V.                                                                                                                                                               |

Notas: < = menor que; Eco-SSL = nivel ecológico de evaluación del suelo; ERE = Evaluación del riesgo para la ecología; LOAEC = concentración de efecto negativo mínimo observado; mg/kg-día = miligramos por kilogramo-día; mg/kg bw/d = miligramos por kilogramo de peso corporal por día; NOAEC = concentración de efecto negativo no observado; PCB = bifenilos policlorados; VRT = valores de referencia de toxicidad; USEPA = Agencia de Protección Ambiental de los Estados Unidos; ww = peso húmedo.

Tabla 2 Datos de la Prueba de Toxicidad Utilizados para Calcular los Valores de Referencia de Toxicidad en Aves

| Parámetros     | VRT Inferior | VRT Superior | Detalles del Estudio de Toxicidad                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|--------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metales</b> |              |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Aluminio (Al)  | 4.17         | 8.33         | No existía un valor de Eco-SSL disponible para el aluminio. Los valores de la NOAEC determinada más baja y la LOAEC fueron obtenidos a partir de una revisión de la bibliografía. Huff et al. (1996) administraron sulfato de aluminio a pollos pequeños a través de la dieta durante un periodo de tres semanas. La NOAEC subcrónica no determinada para el crecimiento fue 41.7 mg/kg-día Al. La LOAEC fue 83.3 mg/kg-día Al. Se aplicó un factor de incertidumbre subcrónica a crónica de 10 al NOAEL y LOAEL.                                                                                                                                                                                                                                                                                                                                                                     |
| Antimonio (Sb) | n/a          | n/a          | No se identificó VRT de antimonio para las aves en la bibliografía revisada.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Arsénico (As)  | 2.24         | 7.38         | El VRT se basó en el NOAEL más bajo de 2.24 mg/kg-día, el cual fue establecido a partir de un estudio en el que se expuso a pollos pequeños a determinados niveles de arsénico a través de los alimentos y los puntos finales de prueba fueron el crecimiento y la reproducción (Holcman y Stibilj, 1997; citado en U.S. EPA 2005b). Se informó que el LOAEL de 7.38 mg/kg/día tuvo efectos en la supervivencia de los tordos de cabeza café expuestos a acetoarseniato de cobre durante 7 meses (Sample et al., 1996).                                                                                                                                                                                                                                                                                                                                                               |
| Bario (Ba)     | 20.8         | 41.7         | No existían Eco-SSL disponibles para los efectos del bario en las especies de aves de la fauna silvestre. La USEPA (2005b) sólo logró encontrar un estudio (Johnson et al. 1960) sobre la toxicidad del bario en las aves. No fue posible calcular un Eco-SSL para las especies de aves de la fauna silvestre ya que este cálculo requiere por lo menos tres resultados para dos especies de prueba. Se registró una LOAEC de 416.5 mg/kg-día Ba y una NOAEC de 208.3 mg/kg-día Ba con respecto a la mortalidad de los pollos pequeños con días de nacidos expuestos al hidróxido de bario a través de la dieta durante 4 semanas (Johnson et al. 1960, citado en Sample et al. 1996). Se aplicó un factor de extrapolación de 10 a la LOAEC y NOAEC para obtener una exposición de subcrónica a crónica.                                                                             |
| Cadmio (Cd)    | 1.47         | 2.37         | Se utilizó un Eco-SSL de la USEPA (2005c) para el cadmio con la finalidad de identificar el VRT inferior. El VRT se derivó de la relación entre la media geométrica de la NOAEC para el crecimiento y la reproducción y la LOAEC determinada más baja para la reproducción, el crecimiento y la supervivencia. El VRT del cadmio fue calculado en 1.47 mg/kg-día Cd tomando como base la media geométrica de los valores de la NOAEC, la cual fue inferior a la LOAEC determinada más baja (USEPA 2005c). La LOAEC determinada más baja para la supervivencia, el crecimiento o la reproducción fue identificada en USEPA 2005c. Leach et al. (1979) administraron cadmio a pollos ( <i>Gallus domesticus</i> ) a través de la dieta durante 12 semanas. Se observó efectos reproductivos (producción de huevos y crías) con la dosis de 2.37 mg/kg-día Cd pero no con dosis menores. |
| Cromo (Cr)     | 2.66         | 2.78         | Se utilizó un Eco-SSL establecido por la USEPA (2008a) para el cromo trivalente a fin de identificar el VRT inferior. El VRT se derivó de la media geométrica de los valores del NOAEL para la reproducción y el crecimiento. El VRT superior se derivó de un estudio realizado por Haseltine et al. (no publicado; citado en USEPA 2008a), en el que se expuso a patos negros a determinados niveles de cromo durante un periodo de 180-190 días a través de los alimentos. El VRT superior (2.78 mg/kg-día) se basa en los efectos reproductivos.                                                                                                                                                                                                                                                                                                                                   |
| Cobalto (Co)   | 7.61         | 7.8          | Se utilizó un Eco-SSL establecido por la USEPA (2005d) para el cobalto con la finalidad de identificar el VRT inferior. Se calculó una media geométrica de 7.61 mg/kg-día Co con respecto a los valores del NOAEL para el crecimiento y la reproducción de las aves (USEPA 2005d). Este valor fue inferior a la LOAEC determinada más baja para los puntos finales de reproducción, crecimiento o supervivencia. Por lo tanto, el valor del VRT fue igual a la media geométrica de los valores del NOAEL para la reproducción y el crecimiento (7.61 mg/kg-día Co). La NOAEC determinada más baja fue 3.89 mg/kg-día Co y la respectiva LOAEC fue 7.8 mg/kg-día Co; por lo tanto, la dosis de esta última fue asignada como el VRT superior.                                                                                                                                          |
| Cobre (Cu)     | 4.05         | 12.1         | Se utilizó un Eco-SSL establecido por la USEPA (2007a) para el cobre con la finalidad de identificar el VRT inferior. Se calculó una media geométrica de 18.5 mg/kg-día Cu con respecto a los valores de la NOAEC para la reproducción y el crecimiento. La media geométrica fue superior a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. El valor del VRT fue igual al de la NOAEC determinada más alta inferior a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia (4.05 mg/kg-día Cu). Dicho umbral se derivó de un estudio realizado por Al-Ankari et al. (1998) sobre la toxicidad reproductiva de los pollos ( <i>Gallus domesticus</i> ) que recibieron dosis de cobre a través de la dieta durante 84 días. La LOAEC para la producción de huevos fue 12.1 mg/kg-día Cu.                        |

Tabla 1-2 Datos de la Prueba de Toxicidad Utilizados para Calcular los Valores de Referencia de Toxicidad en Aves (continuación))

| Parámetros     | VRT Inferior | VRT Superior | Detalles del Estudio de Toxicidad                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------|--------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Plomo (Pb)     | 1.63         | 3.26         | Se utilizó un Eco-SSL establecido por la USEPA (2005e) para el plomo con la finalidad de identificar el VRT inferior. Se calculó una media geométrica de 10.9 mg/kg-día Pb con respecto a los valores de la NOAEC para la reproducción y el crecimiento; sin embargo, este valor era más alto que la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. Por consiguiente, se asignó un valor de VRT igual a la NOAEC determinada más alta inferior a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia (1.63 mg/kg-día Pb). Esta NOAEC se derivó de un estudio realizado por Edens y Garlich (1983) sobre la toxicidad del plomo en pollos ( <i>Gallus domesticus</i> ) que recibieron dosis de plomo por 4 semanas durante una etapa sensitiva; la LOAEC correspondiente para el éxito reproductivo fue 3.26 mg/kg-día Pb.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Molibdeno (Mo) | 3.5          | 35.3         | No existían Eco-SSL disponibles para los efectos del molibdeno en las especies de aves de la fauna silvestre. Se registró una LOAEC de 35.3 mg/kg-día Mo y una NOAEC de 3.5 mg/kg-día Mo para los efectos en la reproducción de los pollos expuestos a dosis de molibdeno de sodio a través de la dieta durante 21 días de la etapa reproductiva (Lepore y Miller 1965, citados por Sample et al. 1996). Se consideró que la exposición era crónica porque se produjo durante una etapa crítica (es decir, durante la reproducción).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Selenio (Se)   | 0.29         | 0.579        | Había un Eco-SSL establecido por la USEPA (2007d) para el selenio. Se calculó una media geométrica de 0.606 mg/kg-día con respecto a los valores del NOAEL para la reproducción y el crecimiento; sin embargo, este valor era superior a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. Por lo tanto, el VRT fue igual al NOAEL determinado más alto inferior a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia (0.29 mg/kg-día Se). La LOAEC correspondiente fue 0.579 mg/kg-día Se para la supervivencia (El-Begearmi y Combs 1982; citados en USEPA 2007d). Este estudio investigó la supervivencia de pollos jóvenes expuestos al selenio.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Estroncio (Sr) | 267          | 2,667        | No se identificó VRT para el estroncio en los documentos de referencia disponibles. Sin embargo, Mora et al. (2007) evaluaron la contaminación por estroncio en los cascarones de los huevos de nueve especies de paserinas (aves de percha) en regiones con altos niveles de estroncio en Arizona, y sostuvieron que las concentraciones elevadas de estroncio en los cascarones podrían afectar a los embriones en etapa avanzada debido a la posible interferencia en el metabolismo del calcio y el crecimiento de los huesos, provocando una reducción en el éxito de las eclosiones así como posibles deformaciones menores en el pico. Se identificó un estudio de toxicidad que podía ser sometido a una derivación de dosis límite; de manera específica, las gallinas White Leghorn que recibieron Sr como parte de su dieta experimentaron una reducción en la producción de huevos, mientras que aquéllas que recibieron 4 por ciento de Sr pusieron un número mayor de huevos agrietados (Mraz et al.1967). Esta exposición se convierte en 2,667 mg/kg-día Sr si se asume un peso corporal de 1.8 kg y un consumo de 120 g/día, y se asume que se trata de una LOAEC crónica (etapa sensitiva durante la reproducción). Se calculó una NOAEC crónica multiplicando la LOAEC crónica por un factor de extrapolación de 0.1. La evaluación del estroncio es mucho más incierta que la de otras sustancias debido a la escasez de datos sobre toxicidad, aunque el punto final de cascarones agrietados observado en el estudio de Mraz et al. (1967) es consistente con el mecanismo de interferencia con los procesos del calcio. |
| Vanadio (V)    | 0.344        | 0.688        | Había un Eco-SSL establecido por la USEPA (2005f) para el vanadio. Se calculó una media geométrica de 1.19 mg/kg-día V con respecto a los valores de la NOAEC para el crecimiento y la reproducción. La media geométrica fue superior a la LOAEC determinada más baja para el crecimiento, la reproducción o la supervivencia. La NOAEC determinada más alta inferior a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia fue 0.344 mg/kg-día V. Dicho umbral fue obtenido a partir de un estudio realizado por Hill (1979), en el cual se administró dosis de vanadio a pollos ( <i>Gallus domesticus</i> ) a través de la dieta por 5 semanas y se midió los niveles de crecimiento (como peso corporal). La LOAEC correspondiente fue 0.688 mg/kg-día V.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Notas: < = menor que; Eco-SSL = nivel ecológico de evaluación del suelo; ERE = Evaluación del riesgo para la ecología; LOAEC = concentración de efecto negativo mínimo observado; mg/kg-día = miligramos por kilogramo-día; mg/kg bw/d = miligramos por kilogramo de peso corporal por día; n/a = no disponible; NOAEC = concentración de efecto negativo no observado; PCB = bifenilos policlorados; TRV = valores de referencia de toxicidad; USEPA = Agencia de Protección Ambiental de los Estados Unidos; ww = peso húmedo.

## 2 ENFOQUE GENERAL

Para identificar los VRT de la fauna silvestre, se utilizó un procedimiento por pasos. En los casos pertinentes, se seleccionó los Niveles Ecológicos de Evaluación del Suelo (Eco-SSLs) establecidos por la USEP para cada CIP (USEPA 2008b), los cuales constituyen una evaluación conservadora, sistemática y rigurosa de la información sobre la toxicidad de la fauna silvestre. En aquellos casos en los que no había Eco-SSLs disponibles, se procedió a revisar la bibliografía disponible para identificar a los VRT candidatos, comenzando por los Parámetros Toxicológicos para la Fauna Silvestre del Laboratorio Nacional de Oak Ridge (Sample et al. 1996) y, de ser necesario, revisando bibliografía detallada adicional de manera complementaria.

Los VRT utilizados en la evaluación del riesgo para los receptores de la fauna silvestre inicialmente se basaron en las concentraciones alimenticias o en las tasas de consumo asociadas a las concentraciones de efectos negativos no observados (NOAEC) para las pruebas con organismos (en adelante denominados VRT inferiores). Los Eco-SSLs “se establecieron con el propósito de preservar la distribución de la exposición y los efectos en las especies y deben utilizarse en la etapa de selección de la evaluación de riesgos ecológicos” (USEPA 2007a). Otros VRT inferiores son igualmente conservadores. Todos estos valores de evaluación de ecotoxicidad tienen como propósito evitar la subestimación de los riesgos, y no buscan identificar niveles de riesgo que justifiquen la adopción de acciones de control. Con la finalidad de proporcionar un contexto adecuado para cualquier exceso identificado de los VRT inferiores, se establecieron VRT adicionales con base en las concentraciones de efecto negativo mínimo observado (LOAEC) (en adelante denominados VRT superiores).

En la revisión de la bibliografía, la identificación de las NOAEC y LOAEC se basó en los efectos biológicamente importantes para los puntos finales de toxicidad relevantes, y no en simples pruebas de importancia estadística. Los umbrales se interpretaron de la siguiente manera:

- Los VRT inferiores brindan una evaluación conservadora de los posibles efectos negativos en los receptores de la fauna silvestre. El exceso de estos VRT podría, o no, provocar efectos negativos, aunque las exposiciones a CIP por debajo de los VRT inferiores podrían derivarse de la ERE con un nivel de confianza adecuado.
- Los VRT superiores brindan una evaluación más realista de los posibles efectos negativos en los receptores de la fauna silvestre pues se relacionan con aquellos consumos alimenticios que, según lo observado, generan efectos negativos en los organismos de prueba sensitivos. Sin embargo, dado que los VRT superiores representan los puntos finales relevantes documentados más sensitivos, éstos no deberán interpretarse como umbrales para las poblaciones o receptores de estudio reales, especialmente en aquellos casos en los que las especies sustitutas no correspondan a los receptores de interés específicos del área.

## **2.1 RESUMEN DE LA DERIVACIÓN DE NIVELES ECOLÓGICOS DE EVALUACIÓN DEL SUELO (ECO-SSL)**

El proceso de derivación de Eco-SSLs de aves y mamíferos se lleva a cabo de forma separada y se presume que proporcionará una protección adecuada para la fauna silvestre terrestre. El proceso de derivación de Eco-SSL constituye un esfuerzo compartido de un grupo de trabajo conformado por distintos grupos de interés, e identifica niveles de evaluación conservadores (incluyendo los VRT para especies de aves y mamíferos de la fauna silvestre). El VRT de los Eco-SSL fue utilizado como el VRT inferior en la evaluación del riesgo para la fauna silvestre. El VRT predeterminado de los Eco-SSL corresponde a la media geométrica de los valores de la concentración de efecto negativo no observado (NOAEC) para la reproducción y el crecimiento. Sin embargo, de conformidad con las reglas de derivación de Eco-SSL, en aquellos casos en los que dicha media geométrica sea superior a las concentraciones de efecto negativo mínimo observado (LOAEC) determinadas más bajas con respecto a la reproducción, el crecimiento o la supervivencia, el VRT de los Eco-SSL deberá ser igual a la NOAEC determinada más alta inferior a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia. En aquellos casos en los que hubiera VRT de Eco-SSL disponibles, el VRT superior deberá ser equivalente a la LOAEC determinada más baja para la reproducción, el crecimiento o la supervivencia.

## **2.2 OTROS VALORES DE REFERENCIA DE TOXICIDAD (VRT) BASADOS EN LA BIBLIOGRAFÍA**

Se llevó a cabo una revisión de la bibliografía sobre estudios de toxicidad en la fauna silvestre realizados para CPI que carecieran de información adecuada de Eco-SSL. El estudio secundario predeterminado para el proceso de derivación de VRT fue definido por Sample et al. (1996), y recomienda un solo estudio para cada CPI (estudios individuales para los receptores de mamíferos y aves). Sample et al. (1996) proporciona un recurso de gran utilidad para la derivación de VRT, así como un análisis transparente del procedimiento de derivación de VRT. Sin embargo, existen algunas discrepancias y/o selecciones cuestionables con respecto a determinados CPI; por consiguiente, se llevó a cabo una prueba de relevancia a través de una revisión de la bibliografía disponible para estos CPI.

A continuación se presenta una serie de consideraciones importantes para la selección de VRT con base en la bibliografía.

### **2.2.1 Efectos Biológicos Medidos en el Estudio**

Los puntos finales utilizados con mayor frecuencia en el estudio fueron la reproducción, el crecimiento y/o el desarrollo. La histopatología, la inducción enzimática, la

inmunosupresión y las respuestas de comportamiento no fueron consideradas puntos finales de medición adecuados debido a su cuestionable elación con los puntos finales de evaluación de riesgos. La no mortalidad no fue uno de los puntos finales de medición preferidos, a menos que se estuvieran evaluando otros efectos sub-letales (pero no observados) en el estudio. Los efectos medidos en el estudio fueron considerados “significativos” únicamente si presentaban una importancia biológica evidente (es decir, eran importantes para el mantenimiento general y la salud de la población). Los efectos estadísticamente importantes de poca o ninguna relevancia para la salud (debido al tamaño reducido de los efectos o los efectos compensatorios<sup>1</sup>) no fueron considerados como puntos finales relevantes. Se dio preferencia a aquellos estudios que proporcionaron una NOAEC y una LOAEC para el efecto de interés (es decir, los umbrales de efectos determinados).

### **2.2.2 Calidad Técnica del Estudio**

Los estudios deberán haber incluido un número suficiente de organismos de prueba así como un mecanismo de control adecuado. El contaminante sometido a investigación deberá haber sido aislado para evitar efectos interactivos. La prueba deberá haberse llevado a cabo con niveles normales de nutrición en la dieta, ya que muchos metales son más biodisponibles en dietas con deficiencia de nutrientes.

### **2.2.3 Método de Administración**

El método de administración utilizado con mayor frecuencia fue la exposición oral en la dieta, a través de los alimentos o el agua para beber, ya que se asume que los receptores recibirán la exposición por esta vía. La exposición oral mediante cápsulas o alimentación forzada (es decir, estudios con sondas) fueron los métodos de administración menos utilizados. Los estudios con inyecciones no fueron considerados como vías de exposición aceptables, ya que la ingesta gastrointestinal es un proceso que influye de manera significativa en la biodisponibilidad y toxicidad.

### **2.2.4 Duración del Estudio**

Los puntos finales de prueba crónicos y sub-crónicos se utilizaron con mayor frecuencia pues se asume, de manera conservadora, que los receptores de la fauna silvestre en los alrededores del Proyecto serán residentes de estas áreas por periodos lo suficientemente largos para experimentar una exposición crónica. Los estudios

---

<sup>1</sup> Un ejemplo es la inhibición temporal del crecimiento durante un periodo de tiempo reducido, la cual es rápidamente compensada a medida que el organismo se desarrolla; en este caso, no se considera que el efecto altere de manera significativa la capacidad de supervivencia y reproducción del organismo, provocando así un impacto insignificante en la población receptora.

crónicos ideales son aquellos que evalúan los efectos que se extienden durante toda la vida o por múltiples generaciones de animales. Debido a que no siempre es posible contar con este tipo de estudios, también se tomó en consideración las pruebas que abarcaban una parte significativa de un periodo de vida o una etapa sensitiva (es decir, el periodo reproductivo o el periodo de desarrollo juvenil).

## **2.3 CONVERSIÓN DE LAS CONCENTRACIONES ALIMENTICIAS A VALORES DE CONSUMO DIARIOS**

El enfoque del coeficiente de peligro utilizado en la presente evaluación de riesgos requiere que los VRT se expresen en términos de consumo diario estandarizado a la masa corporal (es decir, miligramos por kilogramo-día [mg/kg-día]). Sin embargo, en muchos estudios experimentales, la exposición se expresa en términos de la concentración del contaminante en los alimentos o el agua administrada *ad libitum* (es decir, suministro ilimitado) a los organismos de prueba. En estos casos, los cálculos de las tasas de consumo de alimentos o agua debieron convertir la concentración alimenticia en ingesta diaria. En aquellos casos en los que la bibliografía original midió o calculó tales parámetros, estos se aplicaron directamente al cálculo de los VRT. Un segundo enfoque utilizó los datos sobre las tasas de consumo y el peso corporal de otros estudios que realizaron pruebas con las mismas especies y durante las mismas etapas de vida de los organismos. En aquellos casos en los que no se pudo llevar a cabo ninguno de estos dos métodos, se calculó las tasas de consumo utilizando los pesos corporales estimados o medidos así como una escala alométrica para obtener una tasa de consumo diario de alimentos.

## **2.4 FACTORES DE EXTRAPOLACIÓN**

En algunos casos, fue necesario el uso de factores de extrapolación para hacer frente al grado de incertidumbre generado por la escasez de datos. Los factores de extrapolación comúnmente utilizados en el proceso de derivación de los VRT de la fauna silvestre incluyen:

- Extrapolación de LOAEC a NOAEC – se multiplica un factor de extrapolación de 0.1 por la LOAEC para obtener la NOAEC (Sample et al., 1996).
- Extrapolación de subcrónico a crónico – se multiplica un factor de extrapolación de 10 por un VRT subcrónico para obtener un VRT crónico (Sample et al., 1996).
- Extrapolaciones entre especies – Es poco usual que existan datos de toxicidad para las especies receptoras de interés; por consiguiente, a menudo es necesario extrapolar los resultados de las pruebas de toxicidad de especies domésticas (por ejemplo, pollos, patos de collar) a receptores de fauna silvestre. Los factores de extrapolación entre especies no fueron aplicados, en términos de factores de aplicación (incertidumbre) o escalas alométricas con base en el peso corporal.

Tomando en cuenta las afirmaciones de Sample et al. (1996) y la guía preliminar del Ministerio del Medio Ambiente de Ontario (2009) emitida recientemente, no se garantiza la confiabilidad de la escala alométrica de datos de toxicidad.

## **2.5 CONVERSIONES QUÍMICAS**

En algunos casos, es necesario convertir la concentración o dosis total administrada a una exposición base de metales/metaloideos. En la mayoría de estudios de organismos vivos, los metales fueron administrados como sales metálicas solubles. La masa de sustancia considerada en el desarrollo del VRT fue la masa de iones metálicos (por ejemplo, aluminio en lugar del cloruro de aluminio). En algunos casos fue necesario adaptar la concentración total de sales a la concentración de iones metálicos.

### 3 ANÁLISIS TOXICOLÓGICO DE LOS ANFIBIOS

Los lineamientos de calidad del agua del Ministerio de Economía y Finanzas de Panamá y del Consejo Canadiense de Ministros de Medio Ambiente (CCME) se utilizaron con el fin de evaluar los riesgos para la vida acuática. Según estos lineamientos, se hizo posible identificar una lista de contaminantes de interés potencial (CIP) en la línea base y en casos de impacto para la vida acuática. A fin de investigar si las normas de calidad del agua que se utilizaron protegían a los anfibios, se llevó a cabo una revisión del material bibliográfico y se recopiló datos para un subgrupo de CIP (aluminio, arsénico, cobre, plomo y zinc).

Los datos relativos a la toxicidad se obtuvieron de las siguientes fuentes:

- base de datos bibliográfica de la toxicología de reptiles y anfibios (Pauli 2000);
- ecotoxicología de anfibios y reptiles (Sparling 2000, principalmente los capítulos de Birge 2000 y Linder y Grillitsch 2000);
- los informes en línea y borradores de las evaluaciones del riesgo ecológico los cuales utilizaron los valores de referencia de la toxicidad para los anfibios (VRT) (borrador Golder y Cantox 2006; URS 2006 borrador); y
- material bibliográfico científico principal.

Los datos principales no se revisaron si se encontraban incluidos en alguna de las fuentes secundarias arriba mencionadas. Los datos recopilados se revisaron con el fin de eliminar duplicidad, de establecer requerimientos de información adicional (es decir sin información sobre puntos finales o especies), o de corregir información presuntamente incorrecta (es decir errores de transcripción).

El conjunto de datos se enfocó en estudios de laboratorio de inmersión aguda y crónica con diversas especies de anfibios en diferentes etapas de sus vidas (es decir embrionaria, larval y adulta) y con duraciones de exposición. En los efectos se incluyó la mortalidad, desarrollo (por ejemplo retraso en la metamorfosis), conducta (por ejemplo evasión de depredadores, conducta de nado), reproducción (por ejemplo demora en la incubación) y malformaciones; sin embargo no se incluyó los efectos bioquímicos, celulares o fisiológicos (por ejemplo inducción enzimática). La cantidad de valores de toxicidad encontrado en la revisión del material bibliográfico para los CIP oscilaron entre 32 y 75 puntos de datos (aluminio: 40; arsénico: 32; cobre: 75; plomo: 37; zinc: 52).

En la Figura 1 se muestra para cada CIP, los datos de toxicidad recolectados de los anfibios correspondientes y se compara con las normas de la calidad del agua. En el caso del aluminio, arsénico y plomo, todos los valores de toxicidad estuvieron por

encima de las normas de la calidad del agua utilizados. En el caso del cobre y del zinc, los datos de un sólo estudio (Birge 2000) proporcionaron valores de toxicidad por debajo de las normas de calidad del agua; en consecuencia más del 95% de los estudios mostró que las normas de la calidad del agua protegen a los anfibios.

## 1 DESCRIPCIÓN GENERAL

La Evaluación de Riesgo de la Calidad del Aire para la Salud Humana es una evaluación de la exposición a sustancias que se emiten al aire. Este apéndice contiene los métodos y resultados detallados de la Evaluación de Riesgo de la Calidad del Aire para la Salud Humana. La Sección 2.0 incluye la evaluación de los riesgos para la salud humana a corto plazo (agudos) (es decir, exposición de 1 hora y 24 horas) y la Sección 3.0 incluye la evaluación de riesgos para la salud humana a largo plazo (crónicos) para la exposición anual.

Se recogieron datos de monitoreo de la calidad del aire de línea base para material particulado y metales de Río Caimito y el campamento Colina. Sin embargo, los datos de monitoreo de la calidad del aire del campamento Colina estuvieron fuertemente influenciados por actividades previas al Proyecto, tales como la construcción de caminos, por lo tanto, las mediciones no se consideran representativas de las condiciones de línea base (ver Evaluación de Impacto de la Calidad del Aire, Capítulo 9, Sección 1.8). Por consiguiente, las mediciones de material particulado menores a  $10\text{ }\mu\text{m}$  ( $\text{PM}_{10}$ ) del campamento Colina no se han incluido en ninguna de las proyecciones de modelo. Debido a la ubicación alejada del Proyecto propuesto y la falta de desarrollo industrial cerca al puerto propuesto o las instalaciones de la mina, se consideró que los compuestos tales como  $\text{SO}_2$ ,  $\text{NO}_2$  y CO eran insignificantes y, por lo tanto, se asumió que las concentraciones de línea base eran cero.

El programa de monitoreo de la calidad del aire se concentró en el material particulado ( $\text{PM}_{10}$ ) debido a las fuentes existentes de PM en la comunidad tales como cocinas a leña, quema de vegetación y combustión limitada de combustibles. Se midieron concentraciones de  $\text{PM}_{10}$  elevadas durante el monitoreo en la comunidad de Río Caimito que posiblemente se debieron a la quema de vegetación y aerosoles de origen marino. No se midió concentraciones de material particulado menores a  $2.5\text{ }\mu\text{m}$  ( $\text{PM}_{2.5}$ ) en el programa de monitoreo de línea base. Por este motivo, MPSA se ha comprometido a llevar a cabo el monitoreo de  $\text{PM}_{2.5}$  en la comunidad de Río Caimito antes de la construcción del Proyecto para definir mejor las condiciones existentes. Independientemente de este compromiso, se han trasladado las concentraciones de  $\text{PM}_{2.5}$  previstas a la evaluación de impacto asumiendo un valor de fondo insignificante.

En consecuencia, los datos de línea base medidos no se utilizaron en la evaluación de riesgos para la salud humana y se previeron concentraciones anuales de línea base para utilizarse en la evaluación de salud crónica. No se dispone de concentraciones de línea base para la evaluación de salud aguda. Se previeron concentraciones de línea base anuales en el aire para metales a partir de los datos de monitoreo de la calidad de aire disponibles de Río Caimito. Los datos del monitoreo anual de  $\text{PM}_{10}$  de Río Caimito se escalaron de acuerdo a la población de cada una de las comunidades para

determinar la calidad del aire de línea base en cada ubicación. La calidad del aire de línea base en los alrededores del cerco perimétrico se determinó en base a la comunidad más cercana (es decir, San Benito para la mina y Río Caimito para el puerto). También se incluyó datos de la calidad del aire de línea base en los datos de caso de impacto para cada ubicación (Tabla 1-1).

Tabla 1-1      Resumen de las Concentraciones Anuales de Metales de Línea Base en el Aire

| Lugar           | Río Caimito | Nueva Lucha | Nuevo Sinaí | San Benito | Molejones | Coclesito | Alrededores del Cerco Perimétrico de la Mina | Alrededores del Cerco Perimétrico del Puerto |
|-----------------|-------------|-------------|-------------|------------|-----------|-----------|----------------------------------------------|----------------------------------------------|
| Parámetro       |             |             |             |            |           |           |                                              |                                              |

## **2 MÉTODOS Y RESULTADOS DE LA EVALUACIÓN DE RIESGOS PARA LA SALUD HUMANA A CORTO PLAZO**

Se realizaron evaluaciones de los riesgos asociados con la exposición aguda (de 1 hora y 24 horas) para el caso de Impacto ya que no se disponía de datos de calidad del aire de línea base para la exposición aguda.

### **2.1 UMBRALES AGUDOS**

Se compararon concentraciones pico de 1 hora y 24 horas de COV, gases ácidos, metales y HAP con los umbrales agudos basados en la salud disponibles de los siguientes organismos:

- Organización Mundial de la Salud (OMS 2000; OMS 2005);
- Normas de Calidad del Aire de Panamá (Autoridad Nacional del Aire Ambiental de Panamá, 2006);
- Agency of Toxic Substances and Disease Registry (Agencia para el Registro de Sustancias Tóxicas y Enfermedades) (ASTDR 2010, sitio de Internet);
- California Office of Environmental Health Hazard Assessment (Oficina de Evaluación de Peligros Ambientales para la Salud de California) (OEHHA 2008, sitio de Internet);
- Ontario Ministry of Environment and Energy (Ministerio del Medio Ambiente y Energía de Ontario) (OMEE 2005; OMEE 2008); y
- Texas Commission on Environmental Quality (Comisión de Calidad Ambiental de Texas) (TCEQ 2010, sitio de Internet).

Se utilizó la siguiente jerarquía para seleccionar el umbral agudo empleado en la evaluación de riesgos: 1) Panamá 2) OMS, 3) ATSDR, 4) OEHHA, 5) OMEE y 6) TCEQ. Se utilizó principalmente umbrales con puntos finales basados en la salud y se emplearon otros puntos finales tales como el olor sólo en caso de ausencia de puntos finales basados en la salud. En casos en los que no se disponía de estándares de calidad de aire agudos de 1 hora, se utilizó estándares de calidad de 24 horas de manera conservadora como sustitutos para fines de análisis. En casos en los que no se disponía de un estándar agudo de 24 horas, se utilizó un estándar de aire anual de manera conservadora para fines de análisis.

En las Tablas 2-1 y 2-2 se presentan los umbrales de 1 hora y 24 horas basados en la salud y las bases de estos umbrales, respectivamente.

Tabla 2-1      Umbrales de Inhalación Aguda de 1 Hora Basados en la Salud

| Parámetro               | ATSDR <sup>(a)</sup><br>[µg/m³] | OMEE <sup>(b)</sup><br>[µg/m³] | OEHHA <sup>(c)</sup><br>[µg/m³] | TCEQ <sup>(d)</sup><br>[µg/m³] | OMS <sup>(e)</sup><br>[µg/m³] | Panamá<br>[µg/m³] | Base del Umbral                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|---------------------------------|--------------------------------|---------------------------------|--------------------------------|-------------------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gases Ácidos            |                                 |                                |                                 |                                |                               |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| monóxido de carbono     | n/d                             | 36,200                         | 23,000                          | n/d                            | 30,000                        | n/d               | El umbral del OMEE se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en los efectos de angina producidos en personas con enfermedades cardiovasculares conocidas y que se ejercitan en exceso. El umbral de la OMS se basa en la ecuación exponencial Coburn-Foster-Kane que toma en cuenta las variables fisiológicas conocidas que afectan la absorción de monóxido de carbono. El umbral se determinó de manera que no se exceda el nivel de carboxihemoglobina (CoHb) de 2.5%, incluso si una persona se ejercita en forma leve o moderada. |
| dióxido de nitrógeno    | n/d                             | 400                            | 470                             | n/d                            | 200                           | n/d               | El umbral del OMEE se basa en efectos sobre la salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en una mayor reactividad de las vías respiratorias en asmáticos. El umbral de la OMS se basa en una mayor respuesta bronquial en asmáticos.                                                                                                                                                                                                                                                                                                                                 |
| dióxido de azufre       | n/d                             | 690                            | 660                             | n/d                            | n/d                           | n/d               | El umbral del OMEE se basa en efectos sobre la salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en el deterioro de la función de las vías respiratorias en asmáticos                                                                                                                                                                                                                                                                                                                                                                                                        |

| acetaldehído             | n/d                             | n/d                            | 470                             | n/d                            | n/d                           | n/d               | El umbral de la OEHHA se basa en un LOAEL de un estudio con humanos. Los efectos críticos del estudio incluyen irritación sensorial de los bronquios, ojos, nariz y garganta.                                                                                                                                                                                                                                                                                                  |
| acroleína                | 6.9 <sup>(f)</sup>              | n/d                            | 2.5                             | 2.3                            | n/d                           | n/d               | El umbral de la ATSDR se basa en el LOAEL para una disminución de la frecuencia respiratoria e irritación de la nariz y garganta en un estudio con humanos voluntarios. Se modificó el LOAEL para exposición intermitente y se aplicó un factor de incertidumbre. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basó en el LOAEL para irritación ocular subjetiva en humanos voluntarios. |
| benceno                  | n/d                             | n/d                            | n/d                             | 170                            | n/d                           | n/d               | El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo.                                                                                                                                                                                                                                                                                                                                                                      |

| PM <sub>2.5</sub>           | n/d                             | n/d                            | n/d                             | n/d                            | 25                            | n/d                              | El umbral de la OMS se basa en los niveles más bajos en los que se ha demostrado un aumento de la mortalidad total, cardiopulmonar y de cáncer al pulmón con más de 95% de certeza en respuesta a una exposición a material particulado a largo plazo. El valor de 24 horas se infirió a partir de los niveles anuales.                                                                         |
| PM <sub>10</sub>            | n/d                             | n/d                            | n/d                             | n/d                            | 50                            | 150                              | El umbral de la OMS se basa en los niveles más bajos en los que se ha demostrado un aumento de la mortalidad total, cardiopulmonar y de cáncer al pulmón con más de 95% de certeza en respuesta a una exposición a material particulado a largo plazo. El valor de 24 horas se infirió a partir de los niveles anuales. El umbral de Panamá no cuenta con documentación de respaldo disponible. |
| PTS                         | n/d                             | 120                            | n/d                             | n/d                            | n/d                           | 360                              | El umbral del OMEE se basa en la visibilidad; no se cuenta con punto final de salud. El estándar panameño es para la generación térmica de electricidad; sin embargo, no se cuenta con documentación de respaldo.                                                                                                                                                                               |
| <b>Gases Ácidos</b>         |                                 |                                |                                 |                                |                               |                                  |                                                                                                                                                                                                                                                                                                                                                                                                 |
| monóxido de carbono         | n/d                             | 5,233 <sup>(f)</sup>           | n/d                             | n/d                            | 3,333 <sup>(g)</sup>          | n/d                              | El umbral del OMEE se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OMS es una media ponderada en el tiempo determinada de manera que no se exceda el nivel de 2.5% de carboxihemoglobina (umbral para el efecto en la salud humana).                                                                                                       |
| dióxido de nitrógeno        | n/d                             | 200                            | n/d                             | n/d                            | n/d                           | n/d                              | El umbral del OMEE se basa en efectos sobre la salud, pero no se cuenta con documentación de respaldo.                                                                                                                                                                                                                                                                                          |
| dióxido de azufre           | n/d                             | 275                            | n/d                             | n/d                            | 125                           | n/d                              | El umbral del OMEE se basa en efectos sobre la salud y vegetación, pero no se cuenta con documentación de respaldo. El umbral de la OMS se basa en estudios epidemiológicos que muestran efectos respiratorios, pulmonares y de mortalidad.                                                                                                                                                     |
| <b>HAP</b>                  |                                 |                                |                                 |                                |                               |                                  |                                                                                                                                                                                                                                                                                                                                                                                                 |

Tabla 2-2      Umbrales de Inhalación Aguda de 24 Horas Basados en la Salud (continuación)

| Parámetro    | ATSDR <sup>(a)</sup><br>[µg/m³] | OMEE <sup>(b)</sup><br>[µg/m³] | OEHHA <sup>(c)</sup><br>[µg/m³] | TCEQ <sup>(d)</sup><br>[µg/m³] | OMS <sup>(e)</sup><br>[µg/m³] | Panamá <sup>(m)</sup><br>[µg/m³] | Base del Umbral                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|---------------------------------|--------------------------------|---------------------------------|--------------------------------|-------------------------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| benceno      | 7.18 <sup>(h)</sup>             | n/d                            | 325 <sup>(i)</sup>              | n/d                            | n/d                           | n/d                              | El nivel de riesgo mínimo de la ATSDR se basó en el LOAEL para disminución de linfocitos en ratones. El LOAEL se ajustó de manera conservadora de 6 horas para una exposición de 6 días a una exposición de 24 horas y se aplicó un factor de incertidumbre de 300; 10 por el uso de un LOAEL, 3 por la extrapolación de animales a humanos y 10 por sujetos sensibles. El umbral de la OEHHA se basa en efectos sobre la salud (toxicidad reproductiva y del desarrollo).                                            |
| tolueno      | 943 <sup>(i)</sup>              | n/d                            | n/d                             | n/d                            | n/d                           | n/d                              | El umbral de la ATSDR se basa en un NOAEL para efectos neurológicos en adultos expuestos al tolueno por 6 hrs/día. El NOAEL se ajustó de manera conservadora para una exposición de 24 horas y se aplicó un factor de incertidumbre de 10.                                                                                                                                                                                                                                                                            |
| etilbenceno  | 14,467 <sup>(k)</sup>           | 1,000                          | n/d                             |                                | n/d                           | n/d                              | El umbral de la ATSDR se basa en un NOAEL para daño auditivo en ratas expuestas 8 hrs/día, durante 5 días. El NOAEL se convirtió de manera conservadora a una exposición de 24 horas y se aplicó un factor de incertidumbre de 30. El umbral del OMEE se basa en un punto final de salud; sin embargo, no se cuenta con documentación de respaldo.                                                                                                                                                                    |
| xilenos      | n/d                             | 730                            | n/d                             | n/d                            | n/d                           | n/d                              | El umbral del OMEE se basa en un punto final de salud (efectos neurológicos). El umbral se deriva de un estudio ocupacional en humanos en el que trabajadores de una fábrica de botas de caucho, de alambres con recubrimiento de plástico y de operaciones de impresión fueron expuestos a una concentración promedio anual de 62 mg/m³ de xileno durante siete años. Algunos trabajadores mostraron signos de irritación de ojos, garganta y sensación de flotación, así como disminución del apetito (OMEE, 2005). |
| acetaldehído | n/d                             | 500                            | n/d                             | n/d                            | n/d                           | n/d                              | El umbral del OMEE se basa en un efecto sobre la salud, pero no se cuenta con documentación de respaldo.                                                                                                                                                                                                                                                                                                                                                                                                              |

(a) Agency for Toxic Substances & Disease Registry (Agencia para el Registro de Sustancias Tóxicas y Enfermedades) (ASTDR 2010) (sitio de Internet).

(b) Ontario Ministry of Energy and the Environment (Ministerio de Medio Ambiente y Energía de Ontario) (OMEE 2005; OMEE 2008)

(c) California Office of Environmental Health Hazard Assessment (Oficina de Evaluación de Peligros Ambientales para la Salud de California) (OEHHA 2008) (sitio de Internet).

(d) Texas Commission on Environmental Quality (Comisión de Calidad Ambiental de Texas) (TCEQ 2009) (sitio de Internet).

(e) Organización Mundial de la Salud (OMS 2000; OMS 2005).

(f) El umbral de la OMS para monóxido de carbono se basó en 8 horas de exposición (10,000 µg/m³). Este valor se convirtió a 24 horas de exposición utilizando la siguiente ecuación (8/24 x 10,000 = 3,333 µg/m³).

(g) El umbral del OMEE para monóxido de carbono se basó en 8 horas de exposición (15,700 µg/m³). Este valor se convirtió a 24 horas de exposición utilizando la siguiente ecuación (8/24 x 15,700 = 5,233 µg/m³).

(h) El umbral de la ATSDR para benceno (0.009 ppm) se convirtió a µg/m³: 1 ppm = 3,190 µg/m³; el valor también se convirtió a 24 horas utilizando el siguiente cálculo 6/24 x 28.71 µg/m³= 7.18 µg/m³).

(i) El umbral de la OEHHA para benceno (1,300 µg/m³) se basa en 6 horas de exposición. Este valor se convirtió a 24 horas de exposición utilizando la siguiente ecuación (6/24 x1,300 µg/m³= 325 µg/m³).

(j) El umbral de la ATSDR para tolueno (1 ppm) se convirtió a µg/m³: 1 ppm = 3,770 µg/m³; el valor también se convirtió a 24 horas de exposición utilizando el siguiente cálculo 6/24 x 3,770 µg/m³= 943 µg/m³).

(k) El umbral de la ATSDR para etilbenceno (10 ppm) se convirtió a µg/m³: 1 ppm = 4,340 µg/m³; el valor también se convirtió a 24 horas de exposición utilizando el siguiente cálculo 8/24 x 43,400 µg/m³= 14,467 µg/m³).

(l) Ministerio de Medio Ambiente de Ontario, Lista Jurisdiccional de Niveles de Análisis, febrero, 2008; los límites jurisdiccionales promedio de aire ambiental son desarrollados por el Ministerio de Medio Ambiente de Ontario utilizando niveles de análisis de 10 agencias (internacionales, estadounidenses y canadienses). Los niveles de análisis se ajustaron para cumplir con las prácticas estándar en Ontario. Todos los límites jurisdiccionales se convirtieron a 24 horas promediando los periodos mediante los factores de conversión estándar utilizados en el proceso de establecimiento de estándares de aire. De la lista convertida, se eligió el límite jurisdiccional promedio para cada contaminante.

(m) Autoridad Nacional del Aire Ambiental de Panamá, 2006.

Notas: n/d = No disponible.

Se utilizaron umbrales agudos sombreados y en negrita en la evaluación de riesgos. Se utilizó la siguiente jerarquía para seleccionar el umbral empleado en el análisis de datos y la evaluación de riesgos: 1) OMS, 2) ATSDR, 3) OEHHA, 4) OMEE, y 5) TCEQ.

### **2.1.1 Comparación de Concentraciones en el Aire de Corto Plazo con Umbrales Agudos**

Se compararon las concentraciones de 1 hora y 24 horas en el aire previstas para el Caso de Impacto con los umbrales agudos elegidos (Tablas 2-3 y 2-4, respectivamente). Se conservó un parámetro para su posterior evaluación por si una concentración pico prevista de alguna ubicación era mayor al umbral agudo del aire. Un parámetro que se conserva para una futura evaluación se considera un Químico de Interés Potencial (QIP) (Sección 1.1.3).

### **2.1.2 Evaluación de Riesgo Agudo de la Calidad del Aire**

Se realizaron evaluaciones de los riesgos asociados a la exposición aguda a QIP y los resultados se presentan a continuación. Para cada QIP, se calculó un cociente de riesgo (CR) por cada ubicación receptora. Un CR es la proporción entre la exposición que probablemente tenga la persona y el valor de toxicidad de referencia (es decir, la concentración del umbral agudo) que se muestra en la siguiente ecuación.

$$CR = \text{concentración de QIP en el aire } (\mu\text{g}/\text{m}^3) / \text{Concentración del Umbral Agudo } (\mu\text{g}/\text{m}^3)$$

Un valor de CR mayor a uno indica que la exposición es mayor que el umbral. Para parámetros y ubicaciones en los que los valores de CR son mayores que uno, se realiza un mayor análisis para determinar la magnitud del efecto. Se realizaron los siguientes pasos de análisis para determinar si el proyecto tiene un efecto insignificante, bajo, moderado o alto en el potencial de exposiciones agudas aceptables:

- comparación de las concentraciones máximas de los percentiles 95 y 75 en el aire con el rango de umbrales agudos disponibles;
- evaluación del conservadurismo del enfoque de modelamiento de aire utilizado para prever concentraciones futuras;
- evaluación del conservadurismo de los umbrales agudos para ese parámetro; y
- evaluación de los posibles efectos en la salud a corto plazo que pueden ocurrir en las concentraciones previstas.

Las Tablas 2-5 y 2-6 muestran los valores de CR para concentraciones pico de 1 hora y 24 horas, respectivamente, en las comunidades regionales. Las concentraciones pico de una hora exceden los umbrales agudos para dióxido de nitrógeno, cobre y hierro sólo en los alrededores del cerco perimétrico. Las concentraciones pico de veinticuatro horas excedieron los umbrales agudos para material particulado (sólo en los alrededores del cerco perimétrico), acroleína (en San Benito y alrededores del cerco perimétrico), cromo (VI) (en Río Caimito y alrededores del cerco perimétrico) y hierro (sólo en los alrededores del cerco perimétrico).

Tabla 2-3      Análisis de las Concentraciones de 1 Hora en el Aire Para la Evaluación del Caso de Impacto en la Salud Humana y Riesgo Ecológico Para el Proyecto de Cobre de MPSA

| Parámetro                | Umbral de 1 Hr | Río Caimito | Palmilla | Nueva Lucha | Parralito | Nuevo Sinaí | San Benito | Molejones   | Coclesito | Alrededores del Cerco Perimétrico | ¿Conservar Como QIP de Aire? |

<sup>(a)</sup> Los alrededores del cerco perimétrico se consideran como el área alrededor del lindero de la concesión del proyecto donde se realizan las predicciones de aire máximas.

Nota: El texto en negrita y sombreado indica que el valor de CR es mayor a 1.

Las Tablas 2-7 y 2-8 presentan la comparación de concentraciones pico, máximas, de percentil 95, de percentil 75 y la cantidad de horas o días en los que las concentraciones previstas son mayores que los límites de exposición aguda, para concentraciones de 1 hora y 24 horas, respectivamente. Los datos de material particulado no eran adecuados para utilizarse en una evaluación cuantitativa debido a las restricciones mencionadas anteriormente, por lo que se utilizó una comparación con el umbral de análisis para realizar una evaluación cualitativa como se describe más a fondo en la evaluación de la magnitud de los efectos.

**Tabla 2-7 Concentraciones de QIP de 1 Hora Previstas Para el Escenario de Impacto Comparadas con los Límites de Exposición Aguda y la Cantidad de Horas por año en las que se Excede el Límite**

| Parámetro            | Lugar                                            | Límite de Exposición Aguda [µg/m <sup>3</sup> ] | Caso de Impacto                                  |                                                    |                                  |                                   |                                                                               |

| hierro               | alrededores del cerco perimétrico <sup>(d)</sup> | 10                                              | 27.3                                             | 22.8                                               | 8.6                              | 3.4                               | 337                                                                           |

<sup>(a)</sup> La concentración pico es la primera concentración más alta prevista por el modelo de calidad de aire para un período de exposición de 1 hora.

<sup>(b)</sup> La concentración máxima es la novena concentración más alta prevista por el modelo de calidad de aire para un período de exposición de 1 hora. Esta es la estadística que usualmente se compara con las Directrices de Calidad del Aire Ambiental. No incluye los pronósticos considerados como valores atípicos del modelo (debido a condiciones meteorológicas extremas, raras o transitorias).

<sup>(c)</sup> La cantidad máxima de horas en un año en las que las concentraciones pico previstas son mayores que la guía aplicable.

<sup>(d)</sup> Los alrededores del cerco perimétrico se consideran como el área alrededor del lindero de la concesión del proyecto donde se espera que ocurran las concentraciones máximas de químicos en el aire.

<sup>(e)</sup> LEA – Límite de Exposición Aguda.

- (a) La concentración pico es la primera concentración más alta prevista por el modelo de calidad de aire para un período de exposición de 24 horas.
- (b) La cantidad máxima de días en un año en los que las concentraciones pico de 24 horas previstas son mayores que la guía aplicable.
- (c) Los alrededores del cerco perimétrico se consideran como el área alrededor del lindero de la concesión del proyecto donde se espera que ocurran las concentraciones máximas de químicos en el aire.
- (d) LEA – Límite de Exposición Aguda

Los resultados de las evaluaciones de la magnitud de los efectos se presentan en las Tablas 2-9 a 2-14. La magnitud del efecto para los compuestos evaluados fue insignificante o baja en todos los casos.

**Tabla 2-9      Análisis Complementario del Dióxido de Nitrógeno (Efectos Agudos) y Determinación de la Magnitud del Efecto**

| <b>Criterios de Análisis</b>                                        | <b>Comentarios</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| comparación de las concentraciones previstas con los límites agudos | Las concentraciones de los percentiles 95 y 75 previstas no exceden el límite de exposición aguda. Se espera que la concentración de dióxido de nitrógeno pico de 1 hora sea mayor que el umbral agudo para 45 horas por año sólo en los alrededores del cerco perimétrico. El CR para dióxido de nitrógeno en los alrededores del cerco perimétrico es 1.3.                                                                                                                                                                                                                                                                                                                                        |
| conservadurismo en los límites agudos para dióxido de nitrógeno     | Se utilizó el umbral de la OMS ( $200 \mu\text{g}/\text{m}^3$ ) en esta evaluación (OMS 2005). Se han reportado efectos en la salud de humanos luego de 1 hora de exposición a concentraciones de dióxido de nitrógeno mayores que $500 \mu\text{g}/\text{m}^3$ . El menor nivel de exposición a dióxido de nitrógeno que ha dado lugar a un efecto directo en la función pulmonar de asmáticos en más de un estudio de laboratorio fue $560 \mu\text{g}/\text{m}^3$ . Sin embargo, se ha reportado una mayor respuesta bronquial en asmáticos en niveles superiores a $200 \mu\text{g}/\text{m}^3$ , y este valor ha sido conservado como el límite de exposición a corto plazo por la OMS (2005). |
| efectos potenciales del dióxido de nitrógeno en la salud            | Se ha reportado respuesta bronquial en asmáticos en concentraciones mayores que $200 \mu\text{g}/\text{m}^3$ (OMS 2005). Las concentraciones pico de una hora exceden el umbral agudo de la OMS sólo en los alrededores del cerco perimétrico.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| magnitud del efecto                                                 | La concentración pico de 1 hora prevista para dióxido de nitrógeno excede los criterios de calidad de aire elegidos (estándar de aire de la OMS) pero las concentraciones previstas de los percentiles 95 y 75 son mucho menores que aquéllas en las que se observaron efectos en la salud. Además, el CR es sólo ligeramente mayor a 1. De acuerdo con esta información, la magnitud del efecto para dióxido de nitrógeno se considera baja.                                                                                                                                                                                                                                                       |

Notas:  $\mu\text{g}/\text{m}^3$  = Microgramos por metro cúbico; OMS = Organización Mundial de la Salud;  
 CR = Cociente de Riesgo.

**Tabla 2-10 Análisis Complementario del Cobre (Efectos Agudos) y Determinación de la Magnitud del Efecto**

| <b>Criterios de Análisis</b>                                        | <b>Comentarios</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| comparación de las concentraciones previstas con los límites agudos | Las concentraciones de los percentiles 95 y 75 no exceden el límite de exposición aguda. De acuerdo con un período de exposición de 1 hora, se prevé que sólo las concentraciones pico de cobre en los alrededores del cerco perimétrico exceden el límite de exposición aguda para 13 horas al año. El CR para cobre en los alrededores del cerco perimétrico es 3.                                                                                                                                                            |
| conservadurismo en los límites agudos para cobre                    | Se utilizó un umbral de 1 hora de la OEHHA (OEHHA 2008). El umbral de la OEHHA se basa en el NOAEL para fiebre de los vapores metálicos en los trabajadores. Se aplicó un factor de incertidumbre de 10 al NOAEL para individuos sensibles.                                                                                                                                                                                                                                                                                     |
| efectos potenciales del cobre en la salud                           | La exposición ocupacional aguda al polvo de cobre ha dado lugar a efectos en la salud que incluyen sabor metálico o dulce en la boca, irritación de las vías respiratorias superiores y náuseas. Trabajadores de una fábrica expuestos a vapores de cobre durante 1 a 10 horas mostraron síntomas de irritación de las vías respiratorias superiores, fiebre de los vapores metálicos (fiebre, disnea, escalofríos, dolor de cabeza, náuseas, mialgia, tos, falta de aliento, sabor dulce y metálico y vómitos (OEHHA 2008).    |
| magnitud del efecto                                                 | La concentración pico de 1 hora de exposición prevista para cobre excede el umbral agudo, pero las concentraciones previstas de los percentiles 95 y 75 son más bajas que aquéllas en las que se observaron efectos en la salud. El CR para cobre en los alrededores del cerco perimétrico es 3, lo cual se considera representativo de riesgo bajo. De acuerdo con esta información, la magnitud del efecto para cobre se considera baja en los alrededores del cerco perimétrico e insignificante en todos los demás lugares. |

Notas: NOAEL = no observed adverse effect level (nivel de efectos adversos no observados); OEHHA = office of Environmental Health Hazard Assessment (oficina de Evaluación de Peligros Ambientales para la Salud); CR = cociente de riesgo.

**Tabla 2-12 Análisis Complementario de las Acroleínas (Efectos Agudos) y Determinación de la Magnitud del Efecto**

| Criterios de Análisis                                               | Comentarios                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| comparación de las concentraciones previstas con los límites agudos | Las concentraciones de 24 horas de los percentiles 95 y 75 exceden los límites agudos en los alrededores del cerco perimétrico. Las concentraciones de los percentiles 95 y 75 no exceden los límites agudos en San Benito. De acuerdo con un período de exposición de 24 horas, se espera que las concentraciones pico de acroleína excedan el límite de exposición aguda para 197 días al año en los alrededores del cerco perimétrico y para 3 días al año en San Benito. Los CR son de 5 en los alrededores del cerco perimétrico y de 1.4 en San Benito.                                                                                              |
| conservadurismo en los límites agudos para acroleínas               | El límite agudo de 24 horas elegido para acroleínas ( $0.08 \mu\text{g}/\text{m}^3$ ) es del Ministerio de Medio Ambiente de Ontario (OMEE 2008). El límite agudo se basa en un efecto sobre la salud, sin embargo no se provee información alguna sobre la forma en que se infirió de este valor.                                                                                                                                                                                                                                                                                                                                                         |
| efectos potenciales de las acroleínas en la salud                   | La irritación ocular es el punto final más común en humanos luego de la exposición aguda a acroleína (OMEE 2005). La concentración más baja en la que se reportó irritación ocular fue de $137 \mu\text{g}/\text{m}^3$ por 5 minutos (Darley et al. 1960). La irritación de la nariz y garganta, así como otros efectos respiratorios por lo general ocurren a mayores concentraciones que la irritación ocular ( $>340 \mu\text{g}/\text{m}^3$ ). Todas las concentraciones previstas son mucho más bajas que las que mostraron ocasionar efectos en estos estudios. Los efectos potenciales en la salud como resultado del proyecto son insignificantes. |
| magnitud del efecto                                                 | La concentración pico de 24 horas prevista para acroleína excede los criterios de calidad de aire elegidos (directriz basada en la salud del OMEE) pero las concentraciones previstas de los percentiles 95 y 75 son más bajas que aquéllas en las que se observaron efectos en la salud. Los CR son 1.4 y 5 para acroleína en San Benito y los alrededores del cerco perimétrico, respectivamente, los cuales se considera que representan un riesgo bajo. Según esta información, la magnitud del efecto para la acroleína se considera baja.                                                                                                            |

Notas:  $\mu\text{g}/\text{m}^3$  = microgramos por metro cúbico; CR = cociente de riesgo.

**Tabla 2-13      Análisis Complementario del Cromo (VI) (Efectos Agudos) y Determinación de la Magnitud del Efecto**

| <b>Criterios de Análisis</b>                                        | <b>Comentarios</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| comparación de las concentraciones previstas con los límites agudos | Las concentraciones de 24 horas de los percentiles 95 y 75 exceden los límites de exposición aguda en los alrededores del cerco perimétrico. Sin embargo, la concentración de los percentiles 95 y 75 no excede el límite de exposición aguda en Río Caimito. De acuerdo con un período de exposición de 24 horas, se espera que las concentraciones pico de cromo (VI) excedan el límite de exposición aguda para 59 días al año en los alrededores del cerco perimétrico y para 1 día al año en Río Caimito. El CR en los alrededores del cerco perimétrico es de 2 y de 1.1 en Río Caimito. |
| conservadurismo en los límites agudos para cromo (VI)               | No se cuenta con un umbral de 24 horas. Por lo tanto, se utilizó un umbral anual de la OMS ( $0.00025 \mu\text{g}/\text{m}^3$ ). Este es un supuesto sumamente conservador debido a la falta de un umbral de 24 horas. El umbral de la OMS se basa en estudios a trabajadores expuestos al cromo (VI). Se tomó una media geométrica de $4 \times 10^{-2}$ de los diferentes estudios sobre el cáncer al pulmón en humanos como un riesgo unitario creciente.                                                                                                                                   |
| efectos potenciales del cromo (VI) en la salud                      | El principal órgano afectado por el cromo (VI) es el tracto respiratorio (es decir, los bronquios), lo que puede traer como resultado cáncer al pulmón (OMS 2000).                                                                                                                                                                                                                                                                                                                                                                                                                             |
| magnitud del efecto                                                 | El umbral utilizado en esta evaluación es para exposición anual y se empleó de manera conservadora para evaluar riesgos de exposición de 24 horas. Utilizando este valor umbral conservador, se determinaron CR de 1.1 y 2 para Río Caimito y los alrededores del cerco perimétrico, respectivamente, lo cual se considera que representa un riesgo bajo.                                                                                                                                                                                                                                      |

Notas:  $\mu\text{g}/\text{m}^3$  = microgramos por metro cúbico; CR = cociente de riesgo; OMS = Organización Mundial de la Salud.

**Tabla 2-14      Análisis Complementario de Material Particulado (Efectos Agudos) y Determinación de la Magnitud del Efecto**

| Criterios de Análisis                                                            | Comentarios                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Notas:  $\mu\text{g}/\text{m}^3$  = Microgramos por metro cúbico; PM = Material particulado; OMS = Organización Mundial de la Salud.

### **3 MÉTODOS Y RESULTADOS DE LA EVALUACIÓN DE RIESGOS DE LA CALIDAD DEL AIRE PARA LA SALUD HUMANA A LARGO PLAZO**

Se realizaron evaluaciones de los riesgos asociados con la exposición a largo plazo/crónica (anual) para la línea base y los casos de impacto. Los métodos, resultados y comparaciones se presentan a continuación.

#### **3.1 UMBRALES DE AIRE CRÓNICOS E IDENTIFICACIÓN DE QUÍMICOS DE INTERÉS POTENCIAL CRÓNICOS**

Las concentraciones promedio anuales en el aire previstas del caso de Impacto de todos los lugares receptores se compararon con las Concentraciones de Aire basadas en Riesgos (CBR) para la protección de la salud humana. Las CBR se obtuvieron de la U.S. EPA (Agencia de Protección Ambiental de los Estados Unidos) (U.S. EPA 2010b, sitio de Internet), Texas Commission on Environmental Quality (Comisión de Calidad Ambiental de Texas) (TCEQ 2009, sitio de Internet), California Office of Environmental Health Hazard Assessment (Oficina de Evaluación de Peligros Ambientales para la Salud de California) (OEHHA 2008, sitio de Internet) y la Organización Mundial de la Salud (OMS 2000, 2005). Las concentraciones basadas en riesgos utilizan “niveles seguros” de toxicidad o límites de exposición combinados con variables de exposición “estándar” (por ejemplo, pesos corporales, frecuencias de inhalación, ingesta y exposición) para calcular las concentraciones químicas que corresponden a niveles fijos de riesgo.

Se utilizó la siguiente jerarquía para elegir las CBR empleadas en la evaluación de riesgos: 1) OMS, 2) US EPA 3) OEHHA, y 4) TCEQ. Se utilizaron CBR basadas en el olor debido a la falta de una CBR basada en la salud. La Tabla 3-1 muestra un resumen de las CBR seleccionadas que se utilizaron en esta evaluación. En la Tabla 3-2 se muestra el análisis de las concentraciones crónicas en el aire. Si las concentraciones de químicos previstas fueron mayores que las CBR y además mostraron un cambio mayor al 10% con respecto a las concentraciones de fondo previstas, se definieron como Químicos de Interés Potencial (QIP). Se consideró que una comparación con concentraciones 10% por encima de la línea base representaba una evaluación conservadora de si era probable que ocurriera un impacto medible relacionado con el proyecto en la calidad ambiental. Debido a la variabilidad temporal, variabilidad en el muestreo y métodos de laboratorio y la incertidumbre inherente a los modelos predictivos de la calidad de aire, se consideró que era poco probable que cualquier aumento previsto menor a 10% por encima de la línea base reflejara un cambio real en la calidad del aire relacionado con el proyecto. Los contaminantes de interés potencial identificados para el análisis complementario en la evaluación de

riesgos crónicos de inhalación de aire incluyen material particulado, aluminio, cobre y hierro. El aluminio, cobre y hierro se trataron en la evaluación con múltiples medios ya que se encuentran presentes en otros medios (por ejemplo, suelo, agua, sedimentos y alimentos) además del aire. Se conservó el material particulado para una futura evaluación.

### 3.1.1 Evaluación de Toxicidad

La evaluación de toxicidad tiene que ver con la identificación de los efectos potencialmente tóxicos de los químicos y determinar la cantidad de químicos a los que puede estar expuesto un receptor sin experimentar efectos inaceptables (es decir, Valores de Referencia de Toxicidad [VRT]). Los VRT se basan simplemente en efectos críticos observados en estudios a poblaciones humanas o especies animales expuestas.

Los Valores de Referencia de Toxicidad para químicos no cancerígenos se denominan Concentraciones de Referencia (CRf) y los VRT para químicos cancerígenos se denominan Riesgos Unitarios (RU), sin embargo, ninguno de los QIP de aire crónicos identificados en esta evaluación de riesgos es cancerígeno. Una CRf es un estimado de exposición a inhalación continua de un químico por la población humana (incluyendo subgrupos sensibles) que probablemente carezca de un riesgo apreciable de efectos nocivos durante toda una vida. Se recopilaron las CRf disponibles de las siguientes entidades:

- Organización Mundial de la Salud (OMS 2000);
- Niveles de Análisis Regionales de la Agencia de Protección Ambiental de los Estados Unidos (U.S. EPA 2010, sitio de Internet);
- Agencia para el Registro de Sustancias Tóxicas y Enfermedades (ASTDR 2010, sitio de Internet);
- Instituto Nacional de Salud Pública y Medio Ambiente (RIVM 2001); y
- Health Canada (Health Canada 2009).

Se eligieron las concentraciones de referencia de acuerdo con la siguiente jerarquía: 1) OMS, 2) US EPA 3) ATSDR, 4) RIVM, y 5) Health Canada. La Tabla 3-3 muestra las CRf disponibles, elegidas y la base toxicológica de las CRf. Éstas fueron recopiladas sólo para los QIP identificados en la Sección 1.2.1

Tabla 3-1      Umbrales de Inhalación Crónica Basados en la Salud (Concentraciones Basadas en Riesgos)

| arsénico             | 0.0057                          | 0.01                           | 0.015                           | 0.0066                        | n/d                              | El nivel de análisis regional de la USEPA se basa en un nivel de exposición de referencia oral que causó una disminución de la función intelectual en niños de 10 años. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA es para un período de exposición de 9.5 a 10.5 años en base a un LOAEL para disminución de la función intelectual, efectos adversos en el desarrollo neuroconductual en niños. Se aplicó un factor de incertidumbre de 30 al LOAEL; 3 por calcular el LOAEL por análisis cuantitativo de datos de estudios y 10 por variación intraespecies. El umbral de la OMS se basa en poblaciones humanas expuestas en Suecia y los Estados Unidos y su susceptibilidad al cáncer de pulmón.                                                                                                                                                                                                                                                                                                                                                            |
| bario                | 0.104                           | 0.5                            | n/d                             | n/d                           | n/d                              | El nivel de análisis regional de la USEPA se basa en una CRf derivada de un estudio de fetotoxicidad en ratas de 4 meses de edad. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| cadmio               | 0.014                           | 0.01                           | 0.02                            | 0.003                         | n/d                              | El nivel de análisis regional de la USEPA se basó en una CRf derivada de estudios en humanos que mostraron efectos renales. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en un estudio en humanos expuestos de manera ocupacional, durante un período de exposición promedio de 4.1 años para el grupo. Los efectos críticos medidos fueron enfermedades renales y respiratorias. El umbral de la OMS se basa en una evaluación general de datos de trabajadores industriales expuestos al cadmio. El umbral se estableció en un nivel de exposición de 3 µg/m³ para 8 horas, para prevenir la disfunción tubular renal.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| cromo (total)        | n/d                             | 0.1                            | n/d                             | n/d                           | n/d                              | El umbral de la TCEQ para metal de cromo se basa en un punto final de salud, pero no se cuenta con documentación de respaldo.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| cromo VI             | 0.0001                          | 0.01                           | 0.2                             | 0.00025                       | n/d                              | El umbral del nivel de análisis regional de la USEPA se basa en un estudio en ratas que mostró efectos en el sistema respiratorio (lactato deshidrogenasa en el fluido de lavado bronquioalveolar). Se utilizó una concentración de punto de referencia del estudio en ratas, proporción de dosis depositada regional y factores de incertidumbre (300) para derivar una CRf de 1E-4 mg/m³. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en un período de exposición de 90 días basado en un BMC <sub>05</sub> de 12.5 µg/m³ para hiperplasia broncoalveolar en ratas Wister macho. Se calculó una concentración equivalente para humanos de acuerdo con este valor. Luego, se aplicó un factor de 100 a este valor; 3 por incertidumbre subcrónica, 3 por variación interespecies y 10 por variación intraespecies. El umbral de la OMS se basa en estudios a trabajadores expuestos al cromo VI. Se tomó una media geométrica de 4 x 10 <sup>-2</sup> de los diferentes estudios sobre el cáncer de pulmón en humanos como un riesgo unitario creciente. |

Tabla 3-1      Umbrales de Inhalación Crónica Basados en la Salud (Concentraciones Basadas en Riesgos) (continuación)

| Parámetro | USEPA <sup>(a)</sup><br>[µg/m³] | TCEQ <sup>(d)</sup><br>[µg/m³] | OEHHA <sup>(c)</sup><br>[µg/m³] | OMS <sup>(d)</sup><br>[µg/m³] | Panamá <sup>(e)</sup><br>[µg/m³] | Base del Umbral                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| cobalto   | 0.0027                          | 0.02                           | n/d                             | n/d                           | n/d                              | El umbral de los niveles de análisis regionales de la USEPA se basa en un NOAEL (1.9 µg/m3) para disminución de la función pulmonar e irritación de las vías respiratorias en trabajadores. El NOAEL se ajustó utilizando un factor de incertidumbre de 300: 3 por la extrapolación de exposición subcrónica a crónica, 10 por insuficiencias de la base de datos y 10 por variabilidad humana entre individuos. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| cobre     | n/d                             | 1 <sup>(f)</sup>               | 100                             | n/d                           | n/d                              | El umbral de la TCEQ es para polvo y niebla de cobre y se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en un estudio donde los trabajadores expuestos experimentaron la fiebre de los vapores metálicos. De acuerdo a este estudio, se estableció un valor límite umbral (NOAEL) de 1 mg/m³ para polvo de cobre. Luego, se aplicó un factor de incertidumbre de 10 a este valor por la variabilidad en la respuesta individual.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| hierro    | n/d                             | 1                              | n/d                             | n/d                           | n/d                              | El umbral de la TCEQ es para hierro (sales solubles) y se basa en un punto final de salud, pero no se cuenta con documentación de respaldo.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| plomo     | n/d                             | n/d                            | n/d                             | 0.5                           | n/d                              | El umbral de la OMS se basa en asegurar que por lo menos 98% de una población expuesta tiene niveles sanguíneos que no exceden los 100 µg/L. En consecuencia, el nivel de plomo anual promedio en el aire no debería exceder los 0.5 µg/m³. Este umbral se basa en la suposición de que el límite superior de sangre no antropogénica es de 30 µg/L.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| manganeso | 0.0104                          | 0.2                            | 0.09                            | 0.15                          | n/d                              | El nivel de análisis regional de la USEPA se pasa en un estudio ocupacional del deterioro de la función neuroconductual luego de la exposición a óxidos y sales de manganeso. Un efecto crítico de este estudio fue el deterioro de la función neuroconductual. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en un estudio del deterioro de la función neuroconductual en humanos expuestos al manganeso 8 horas al día en el lugar de trabajo. La concentración de exposición ajustada para el tiempo fue de 26 µg/m³. Se utilizó un factor de incertidumbre acumulativo de 300: √ 10 por la conversión de subcrónico a crónico, 10 por la mayor absorción y depósito pulmonar en niños y 10 por la mayor susceptibilidad de los niños a la neurotoxicidad. El umbral de la OMS se basa en efectos neurotóxicos observados en trabajadores expuestos de manera ocupacional utilizando un NOAEL estimado de 0 µg/m³. El NOAEL se ajustó dividiéndolo por un factor de 4.2 para adaptarlo a exposición continua, y por un factor de incertidumbre de 50: 10 por la variación interindividual y 5 por los efectos en el desarrollo de niños más pequeños. |
| mercurio  | 0.062                           | 0.025                          | 0.03                            | 1                             | n/d                              | El umbral del nivel de análisis regional de la USEPA se basa en un estudio ocupacional en humanos. Los efectos críticos incluyen temblor de manos y un aumento de la alteración de la memoria. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en el deterioro de la función neuroconductual en humanos expuestos al mercurio 8 horas al día 5 días a la semana en el lugar de trabajo. Se aplicó un factor de incertidumbre de 300 al LOAEL de la OEHHA (un factor de 10 como defecto por un efecto severo y falta de NOAEL, y un factor de 30 por variación intraespecies). El umbral de la OMS se basa en el LOAEL para inhalación de vapor de metil mercurio. Se aplicó un factor de 20 (10 por incertidumbre debido a sensibilidades variables en poblaciones de alto riesgo y un factor de 2 por la extrapolación de un LOAEL a un NOAEL).                                                                                                                                                                                                                                                                                                           |
| molibdeno | n/d                             | 5                              | n/d                             | n/d                           | n/d                              | El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| níquel    | 0.094                           | 0.015                          | 0.05                            | 0.025                         | n/d                              | El nivel de análisis regional de la USEPA se basa en un NOAEL para inflamación crónica activa y fibrosis pulmonar en ratas. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en un LOAEL para patología pulmonar, nasal epitelial y linfática en ratas hembra y macho. El LOAEL se convirtió a una concentración equivalente para humanos de 1.6 µg/m³. Se aplicó un factor de 30 por incertidumbre del LOAEL (3 por variabilidad interespecies y 10 por variabilidad intraespecies). El umbral de la OMS se basó en estimados de exposición y riesgo en poblaciones industriales para casos reportados de cáncer al pulmón.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Tabla 3-1      Umbrales de Inhalación Crónica Basados en la Salud (Concentraciones Basadas en Riesgos) (continuación)

| Parámetro | USEPA <sup>(a)</sup><br>[µg/m³] | TCEQ <sup>(d)</sup><br>[µg/m³] | OEHHA <sup>(c)</sup><br>[µg/m³] | OMS <sup>(d)</sup><br>[µg/m³] | Panamá <sup>(e)</sup><br>[µg/m³] | Base del Umbral                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| selenio   | 4.2                             | 0.2                            | 20                              | n/d                           | n/d                              | El nivel de análisis regional de la USEPA se basa en un estudio de humanos que consumen selenio. El umbral de inhalación crónica se basa en el umbral oral crónico para selenosis clínica del hígado, sangre, piel y SNC. El umbral de la TCEQ se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OEHHA se basa en un estudio de 400 personas expuestas a diversos niveles de selenio ambiental. La exposición ocasionó selenosis del hígado, sangre, piel y sistema nervioso central. Se aplicó un factor de incertidumbre de 3 al NOAEL por variabilidad intraespecies. |

| uranio    | 0.062                           | 0.05                           | n/d                             | n/d                           | n/d                              | El nivel de análisis regional de la USEPA se basa en un NOAEL (0.05 mg/m³) para efectos histológicos y bioquímicos en perros. Se aplicaron factores de incertidumbre al NOAEL; 3 por extrapolación de animales a humanos y 10 por variabilidad en humanos. El NOAEL también se ajustó para exposición continua con el fin de derivar un umbral de inhalación. El umbral de la TCEQ para uranio soluble se basa en un punto final de salud, pero no se cuenta con documentación de respaldo.                                                                                                                                 |
| vanadio   | n/d                             | 0.05                           | n/d                             | 1                             | n/d                              | El umbral de la OEHHA se basa en una mayor producción de mucosidad en humanos. El umbral de la TCEQ para material particulado se basa en un punto final de salud, pero no se cuenta con documentación de respaldo. El umbral de la OMS se basa en un LOAEL de 20 µg/m³ en base a síntomas crónicos de las vías respiratorias superiores. Se aplicó un factor de 20 ya que los efectos observados en esta concentración fueron mínimos y no se ha identificado una población susceptible.                                                                                                                                    |

(e) Health Canada. 2009 (Health Canada 2009).

(f) La fuente de la CRf se explica en la sección de punto final toxicológico, ya que se disponía de CRf de otras jurisdicciones.

Notas: n/d = No disponible. Se utilizaron CRf en negrita en la evaluación de riesgo. Evaluación de Exposición

### 3.1.2 Evaluación de la Exposición

La evaluación de exposición es el proceso de estimar la exposición de un receptor humano a una sustancia bajo un escenario de exposición determinado. Se llevó a cabo una evaluación de exposición para cada QIP identificado (Sección 1.2.1). Las exposiciones se calcularon en base a concentraciones promedio anuales previstas. Se evaluó la vía de inhalación de aire crónica comparando directamente las concentraciones promedio anuales con las CRf.

### 3.1.3 Caracterización de Riesgos

Los efectos crónicos en la salud se evaluaron calculando CR. Un CR es la proporción entre la exposición que probablemente tenga la persona y la cantidad de exposición que se considera segura. No se prevé riesgos para la salud si el CR es menor a uno.

Cuando el CR es mayor a uno, los escenarios plantean un interés potencial y requieren mayor evaluación. Sin embargo, los valores de CR mayores que uno no necesariamente indican que ocurrirán efectos nocivos para la salud, puesto que se ha incluido un amplio margen de seguridad en su estimación.

Durante la etapa de caracterización de riesgos, se calcularon valores de CR para QIP no cancerígenos como la proporción de la concentración prevista en el aire con respecto a la CRf, de acuerdo con la siguiente ecuación:

$$\text{CR} = \text{concentración de QIP en el aire } (\mu\text{g}/\text{m}^3) / \text{CRf } (\mu\text{g}/\text{m}^3)$$

Un CR menor o igual a 1 indica que la exposición estimada es menor a la concentración de referencia, lo que significa impactos insignificantes en la salud.

### 3.1.4 Resultados de la Evaluación de Inhalación

En la Tabla 3-4 se muestran los cocientes de riesgo de inhalación crónica para todos los QIP. Los contaminantes con cocientes de riesgo mayores que uno (por ejemplo, PM<sub>10</sub>) se conservaron para una evaluación más exhaustiva (Tabla 3-5). Los datos de material particulado no eran adecuados para utilizarse en una evaluación cuantitativa debido a las restricciones mencionadas anteriormente, por lo que se utilizó una comparación con el umbral de análisis para realizar una evaluación cualitativa como se describe más a fondo en la evaluación de la magnitud de los efectos. Los resultados de la evaluación de aire crónica para PM<sub>10</sub> se resumen a continuación:

- Se identificó que PM<sub>10</sub> tiene un CR mayor a 1 en Coclesito y en los alrededores del cerco perimétrico (CR=1.6 y 1.1 respectivamente). No se disponía una concentración de referencia para material particulado por lo que los CR se calcularon utilizando los criterios de análisis panameños para PM<sub>10</sub> con fines de análisis. Debido a los CR bajos, es probable que los riesgos para la salud asociados con estas excedencias sean bajos.

Tabla 3-4 Cocientes de Riesgo de Inhalación Crónica

| Parámetro            | CRf<br>[µg/m³] | Cocientes de Riesgo Para Concentraciones Crónicas en el Aire en Comunidades Regionales |          |             |           |             |            |               |           |                                   |

|                      |                | Río Caimito                                                                            | Palmilla | Nueva Lucha | Parralito | Nuevo Sinaí | San Benito | Los Molejones | Coclesito | Alrededores del Cerco Perimétrico |
| Material Particulado |                |                                                                                        |          |             |           |             |            |               |           |                                   |
| PM <sub>10</sub>     | 50             | 5.87E-01                                                                               | 5.16E-01 | 6.85E-01    | 5.18E-01  | 8.11E-01    | 5.12E-01   | 4.11E-01      | 1.57E00   | 1.10E00                           |

(a) Concentración basada en riesgos de la TCEQ.  
(b) La CRf se derivó de una RfD de 0.7 mg/kg al día de la US EPA NCEA (2006 utilizando el peso corporal y frecuencia de inhalación para un niño pequeño (0.7 / 9.3 \*16.5 = 1.242 mg/m³).  
Notas: Las unidades están en µg/m3. Los cocientes de riesgo mayores que 1 están en negrita.

Tabla 3-5 Análisis Complementario de PM<sub>10</sub> (Efectos Crónicos) y Determinación de la Magnitud del Efecto

| Criterios de Análisis                                                 | Comentarios                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| comparación de las concentraciones previstas con los límites crónicos | - Los CR crónicos fueron de menores a 1 en todos los lugares excepto por Coclesito y los alrededores del cerco perimétrico donde éstos fueron de 1.6 y 1.1 respectivamente.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| conservadurismo en los límites crónicos para material particulado     | - El umbral de PM <sub>10</sub> (50 µg/m³) utilizado para fines de análisis es de la Autoridad Nacional de Aire Ambiental de Panamá (2006).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| efectos crónicos potenciales del material particulado en la salud     | - Los efectos en la salud relacionados con la exposición a largo plazo a PM son principalmente efectos respiratorios y cardiovasculares, así como mortalidad (OMS 2005) y pueden asociarse a cualquier incremento de las concentraciones de PM sobre el fondo;<br>- Las relaciones epidemiológicas pueden utilizarse para calcular el aumento de incidencias anuales de mortalidad y morbilidad con respecto a los cambios previstos de las condiciones de fondo;<br>- Sin embargo, de acuerdo con una búsqueda de material bibliográfico, aún no se han desarrollado relaciones epidemiológicas para países centroamericanos y la extrapolación de un contexto norte/sudamericano de centros urbanos con un alto porcentaje de fuentes relacionadas con combustión no es adecuada para la selva panameña.                                                                                                                                                                         |
| magnitud del efecto                                                   | - La concentración pico anual prevista para material particulado (PM <sub>10</sub> ) excede los criterios de calidad de aire elegidos en Coclesito y los alrededores del cerco perimétrico, sin embargo, el CR es sólo ligeramente mayor a 1;<br>- También existe incertidumbre asociada a las concentraciones de línea base de PM <sub>10</sub> previstas ya que se han escalado de datos recolectados en Río Caimito en base al tamaño de la población, debido a problemas con la calidad de los datos con respecto a las muestras recogidas en el campamento Colina.<br>- Debido a las restricciones antes mencionadas, los datos no son adecuados para utilizarse en una evaluación cuantitativa de la relación epidemiológica para determinar un aumento en las incidencias de mortalidad y morbilidad;<br>- De acuerdo con esta información, la magnitud el efecto para PM <sub>10</sub> se considera baja y la incertidumbre subyacente se tratará con monitoreo adicional. |

<sup>(a)</sup>
Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Nota: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

(a) Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Nota: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup>      Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:    Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

          Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup>      Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:    Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup>      Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:    Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

          Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup>    Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:   Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

         Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Nota: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

**Tabla 13    Dosis de Exposición y Cocientes de Peligro/Valores de ILCR para Adultos, Comunidad Costera, Proyecto Mina de Cobre Panamá, Caso de Impacto para Panamá - Estimación de Exposición en el Límite Superior**

(a) Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Nota: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Nota: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

**Tabla 18**
**Dosis de Exposición y Cocientes de Peligro/Valores de ILCR para Niños Pequeños, Línea de Cerco, Proyecto Mina de Cobre Panamá, Caso de Impacto para Panamá - Estimación de Exposición en el Límite Superior (continuación)**

<sup>(a)</sup>
Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

Tabla 20    Resumen de Cocientes de Peligro/Valores de ILCR para Todos los Receptores, Proyecto Mina de Cobre Panamá, Caso de Impacto para Panamá - Estimación de Exposición en el Límite Superior

(a)    Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:    Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

          Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup>
Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

**Tabla 24    Dosis de Exposición y Cocientes de Peligro/Valores de ILCR para Niños Pequeños, Comunidades Indígenas, Proyecto Mina de Cobre Panamá, Caso de Línea Base para Panamá - Estimación de la Exposición de Tendencia Central**

<sup>(a)</sup>    Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup>
Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:
Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

(a)    Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:   Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

         Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup>    Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup>      Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:    Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup>    Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:   Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

         Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup>      Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:   Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

<sup>(a)</sup>    Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas:   Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

         Los valores resaltados y en negrita indican que la estimación de riesgo excede el valor ILRC (ILCR > 1E-5)

<sup>(a)</sup> Calificador químico - NC significa no cancerígeno; C significa cancerígeno; NA significa que no se ha evaluado porque la sustancia no era cancerígena o porque no se midió en un medio particular.

Notas: Los valores en negrita y en cursiva indican que las estimaciones de riesgo exceden el cociente o índice de peligro objetivo (CP o IP > 1).

## **1 DESCRIPCIÓN GENERAL**

Para efectos de este estudio, se procedió a evaluar los datos de la calidad del agua previstos comparándolos con los valores reglamentarios relevantes y aplicables, así como con la calidad del agua de línea base. Durante el proceso, los contaminantes de interés potencial (COPC por sus siglas en inglés) se identificaron como aquellas sustancias que excedían el valor reglamentario más bajo y que asimismo, mostraban un incremento del 10% o más sobre la concentración de línea base promedio en cualquiera de los lugares de muestreo. La comparación de los valores obtenidos con los valores reglamentarios se puede considerar como una evaluación conservadora de la posibilidad de que las concentraciones predichas tengan efectos adversos, mientras que, por otro lado, la comparación de los valores obtenidos con las concentraciones que pasaban el 10% de los valores de línea base se puede considerar como una evaluación conservadora de la posibilidad de que ocurra un impacto medible en la calidad del agua relacionado con el Proyecto. Dada la variabilidad temporal en la calidad del agua, la variabilidad de los métodos de muestreo y de los análisis de laboratorio, y la incertidumbre inherente existente en todo modelo de predicción de la calidad del agua, se consideró que todo aumento predicho que sea menor al 10% de los valores de línea base no representaba un cambio real en la calidad del agua que esté relacionado con el Proyecto.

Los elementos que se identificaron como COPC fueron el aluminio, el cadmio, el cobre y el molibdeno. Para determinar si era adecuado realizar ajustes en los criterios de los análisis específicos al área y evaluar el grado en que las concentraciones previstas indicaban un posible riesgo de efectos adversos en la vida acuática, se realizó un estudio de las bases de los criterios de análisis de estas sustancias (Sección 2.0). Luego se procedió a revisar el material bibliográfico científico relevante para evaluar con mayor detalle los COPC que, según la evaluación de análisis realizada, podían causar efectos adversos en la vida acuática (Sección 3.0). El objetivo de la revisión del material bibliográfico fue el de evaluar la incertidumbre inherente que se tiene al aplicar criterios de análisis norteamericanos (CCME 2008, USEPA 2007) para evaluar las concentraciones de COPC en las aguas superficiales panameñas. Finalmente, se dio ciertas recomendaciones para abordar la incertidumbre residual en la evaluación de la calidad del agua prevista (Sección 4.0).

## 2 EVALUACIÓN DE LOS CRITERIOS DE ANÁLISIS

La Tabla 2-1 presenta una evaluación de los criterios de análisis y de las concentraciones de COPC previstas. A continuación, se proporciona un resumen de los hallazgos de tal evaluación:

- **Aluminio** – El valor guía CCME (2008) para el aluminio depende del pH. Existen dos valores guía, los cuales se pueden aplicar a las aguas superficiales del área de estudio principal. El valor guía de 0.01 mg/L para aguas con un pH mayor a 6.5 se basa en un valor propuesto en un primer momento por la Agencia de Protección Ambiental de Estados Unidos (USEPA, por sus siglas en inglés, 1973), mientras que el valor guía de 0.005 mg/L para aguas con pH menores que 6.5 se basa en la concentración sin efecto para el sapo, *Bufo americanus* (Clark y LaZerte 1985).

Se previó que, durante la fase de cierre, la cuenca hidrográfica del Río Caimito podría presentar valores mayores a los valores guía CCME, y a las concentraciones de base en los nodos W3-2, W-3, W8 y W20 (ver desglose específico de las fases de la mina en la Tabla 2-1). Las concentraciones de aluminio previstas en estos cuatro nodos durante esta fase del Proyecto (0.3 mg/L en todos los casos), representan concentraciones mayores a los valores guía de la calidad del agua que pueden considerarse relativamente importantes. Sin embargo, el hecho de que las concentraciones de aluminio de línea base (0.2 mg/L) excedan el valor CCME por un factor de entre 20 y 40 sugiere que la biota que habita en estas aguas probablemente no es muy sensible al aluminio. Además, el incremento previsto en las concentraciones de aluminio durante la etapa de cierre (0.3 mg/L en comparación con 0.2 mg/L de la línea base) representa un cambio en el límite de precisión de las previsiones (es decir, a nivel de los décimos de un mg/L) y por lo tanto, probablemente se encuentra dentro de los límites de incertidumbre en el modelamiento de la calidad del agua. Tomando como base estas consideraciones, el riesgo potencial que representan las concentraciones de aluminio previstas se considera incierto, aunque probablemente bajo.

- **Cadmio** – El valor guía CCME (2008) para el cadmio (0.017 µg/L) se obtuvo multiplicando la concentración más baja de efectos observables (LOEC, por sus siglas en inglés) de 0.17 µg/L para el organismo más sensible (*Daphnia magna*; Biesinger y Christensen 1972) por un factor de seguridad de 0.1. Ninguno de los estudios utilizados para inferir el valor guía observó efectos en concentraciones menores a los 0.17 µg/L.

Tabla 2-1      Resumen de la Evaluación de los Criterios de Análisis Para los Contaminantes de Interés Potencial (COPC)

| COPC     | Criterio de Análisis                                                            | Bases de los Criterios                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Evaluación                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aluminio | valor guía CCME para la protección de vida acuática en agua dulce               | El valor guía CCME para el aluminio se basa en el pH. El valor guía es de 0.005 mg/L para aguas con pH menor a 6.5, y 0.01 mg/L para aguas con pH igual o mayor que 6.5. Algunas concentraciones previstas fueron mayores a 0.1 mg/L y también excedieron los valores guía panameños (0.1 mg/L para las Clases 1-C y 2-C; 0.2 mg/L y la Clase 3-C).                                                                                                                                                                                                                                                                                                                                           | El valor guía CCME proviene del CCREM (Consejo Canadiense de Ministros de Recursos Naturales y Ambiente, por sus siglas en inglés, 1987). El valor guía de 0.01 mg/L para aguas con pH mayor que 6.5 se basa en un límite propuesto primero por la USEPA (1973), mientras que la guía de 0.005 mg/L se basa en la concentración sin efecto para el sapo, <i>Bufo americanus</i> (Clark y LaZerte 1985).<br>Las únicas excedencias de los valores guía CCME y de las concentraciones de línea base se presentan en cuatro nodos de la cuenca hidrográfica del Río Caimito:<br>- W3-2 (años de cierre 31-38 y 39-42, >43 [sólo máximo]);<br>- W3 (años de cierre 31-38 y 39-42, >43 máximo [sólo máximo]); y<br>- W8 (años de cierre 31-38 y 39-42, >43 [sólo máximo]).<br>- W20 (años de cierre 39-42 [sólo máximo])<br>Las concentraciones previstas en estos nodos (0.3 mg/L en todos los casos) representan incrementos relativamente pequeños comparados con la línea base (0.2 mg/L).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| cadmio   | valor guía CCME para la protección de vida acuática en agua dulce (provisional) | El valor guía CCME para el cadmio depende de la dureza del agua. La ecuación utilizada para pronosticar el valor guía de la calidad del agua es: $= 10^{(0.86 \times \log(\text{dureza}) - 3.2)}$ (en unidades de µg/L). El valor guía CCME (0.017 µg/L) asume una dureza de 48.5 mg/L. Este valor se puede ver incrementado en situaciones en la que se presente una mayor dureza en el agua.<br>El valor guía panameño más bajo para el cadmio es 1 µg/L, mientras que la concentración más alta prevista es de 0.2 µg/L.                                                                                                                                                                   | La guía CCME se obtuvo multiplicando una concentración más baja de efectos observables (LOEC) de 0.17 µg/L (Biesinger y Christensen 1972) para el organismo más sensible al cadmio, <i>Daphnia magna</i> , por un factor de seguridad de 0.1 (CCME 1991). A esta guía se le dio un estatus provisional ya que la concentración de cadmio en el agua no se verificó durante la exposición.<br>Si los CP (cocientes de peligro) se calculan sobre la base de las concentraciones de agua previstas empleando una LOEC de 0.17 µg/L, se puede considerar que todos los CP están por debajo de 1, excepto en tres nodos de la cuenca hidrográfica del Río Caimito:<br>- W3 (años de operaciones 0-27; años de cierre 28-30; 31-38; 39-42, >43 [sólo máximo]);<br>- W-3-2 (años de operaciones 0-27; años de cierre 28-30; 31-38; 39-42 >43 [sólo máximo]); y<br>- W8 (años de operaciones 0-27; años de cierre 28-30; 31-38; 39-42, >43 [sólo máximo]).<br>Las concentraciones más altas previstas en estos nodos (0.2 a 0.3 µg/L) se encuentran dentro de un factor de dos del LOEC para la especie más sensible (0.17 µg/L).                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| cobre    | valor guía CCME para la protección de vida acuática en agua dulce               | El valor guía CCME del cobre para la protección de la vida acuática depende de la dureza del agua. El valor guía es:<br>- 0.002 mg/L a una dureza de 0–120 mg/L de CaCO <sub>3</sub> (agua blanda a mediana);<br>- 0.003 mg/L a una dureza de 120–180 mg/L de CaCO <sub>3</sub> (agua dura); y<br>- 0.004 mg/L a una dureza >180 mg/L de CaCO <sub>3</sub> (agua muy dura).<br>El valor guía panameño más bajo es de 0.01 mg/L. El Criterio de Calidad de Agua Dulce para la Vida Acuática de la USEPA para el Cobre (USEPA 2007a,b) se basa en un Modelo del Ligando Biótico (BLM) y es de 0.0023 mg/L. Se calculó los criterios de calidad del agua específicos del área utilizando el BLM. | El valor guía CCME (2008) para el cobre en agua blanda (0.002 mg/L) se basa en un valor recomendado por Demayo y Taylor (1981), y se considera que no representa los últimos avances científicos en la toxicología del cobre. El Criterio de Calidad del Agua de la USEPA se basa en el Modelo del Ligando Biótico (BLM), un modelo de biodisponibilidad de metales que utiliza las características de las aguas receptoras para calcular los Criterios Continuos Crónicos (CCC) específicos del área.<br>Mediante el uso del BLM, se desarrollaron los siguientes Criterios Continuos Crónicos específicos para las cuencas hidrográficas:<br>- 0.00158 mg/L para la cuenca hidrográfica del Río Petaquilla;<br>- 0.00223 mg/L para la cuenca hidrográfica del Río San Juan; y<br>- 0.00432 mg/L para la cuenca hidrográfica del Río Caimito.<br>Estos valores CCC específicos para las cuencas hidrográficas son similares en magnitud a los valores guía para el cobre total adoptados por la CCME. La diferencia es que los valores CCC tienen el propósito de proporcionar una base para la evaluación de las concentraciones de cobre disuelto, que se espera sean menores a las concentraciones de cobre total. La comparación de las concentraciones de cobre total con los valores CCC representa, por lo tanto, una evaluación conservadora de la posibilidad de que ocurran efectos adversos en la vida acuática. El grado de conservadurismo inherente en esta comparación depende de la fracción de cobre total que se encuentra en la fase disuelta. |

Tabla 2-1      Resumen de la Evaluación de los Criterios de Análisis Para los Contaminantes de Interés Potencial (COPC) (continuación)

| COPC      | Criterio de Análisis                        | Bases de los Criterios                                                                                                                                                                                                                                                                                                                                                                                   | Evaluación                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |                                             |                                                                                                                                                                                                                                                                                                                                                                                                          | <p>Aunque las concentraciones de cobre total previstas exceden los CCC específicos de las cuencas hidrográficas en diversos nodos de las cuencas hidrográficas de los ríos Petaquilla y San Juan/Botija, tales concentraciones no exceden los valores de línea base en estas ubicaciones. En la cuenca hidrográfica del Río Caimito, los valores que exceden tanto el CCC como de las concentraciones de línea base se presentan en:</p> <ul style="list-style-type: none"><li>- W3 (años de operaciones 0-27, 28-30; años de cierre 31-38, 39-42, y &gt;43). Las concentraciones previstas promedio son de 0.01 mg/L, mientras que los valores máximos son de 0.02 mg/L. Las concentraciones máximas (0.02 mg/L) son más altas en los años de cierre 31-38, 39-42, &gt;43. La concentración de la calidad del agua de línea base en esta ubicación es de 0.003 mg/L.</li><li>- W3-2 (años de operaciones 0-27, 28-30; años de cierre 31-38, 39-42, y &gt;43). Las concentraciones previstas promedio son de 0.01 mg/L, mientras que los valores máximos son de 0.02 mg/L. Las concentraciones máximas (0.02 mg/L) son más altas en los años de cierre 31-38, 39-42, &gt;43. La concentración de la calidad del agua de línea base en esta ubicación es de 0.003 mg/L.</li><li>- W8 (años de operaciones 0-27, 28-30; años de cierre 31-38, 39-42, y &gt;43). Las concentraciones previstas promedio son entre 0.004 mg/L (cierre &gt;43) y 0.01 mg/L (años de cierre 31-38 y 39-42), mientras que los valores máximos son de 0.01 mg/L a lo largo de toda la vida de la mina (operaciones y cierre/post-cierre). La concentración de la calidad del agua de línea base en esta ubicación es de 0.003 mg/L.</li><li>- W13 (años de operaciones 0-27, 28-30; años de cierre 31-38, 39-42, y &gt;43). Las concentraciones previstas promedio son entre 0.004 mg/L (años de operaciones 0-27) y 0.006 mg/L (años de cierre 31-38), mientras que los valores máximos variaron entre 0.005 (años de operaciones 0-27 y años de cierre &gt;43) y 0.006 mg/L (años de operaciones 28-30; años de cierre 31-38 y 39-42). La concentración de la calidad del agua de línea base en esta ubicación es de 0.003 mg/L.</li><li>- W20 (años de operaciones 0-27, 28-30; años de cierre 31-38, 39-42 y &gt;43). Las concentraciones previstas promedio son entre 0.005 mg/L (años de operaciones 0-27 y 28-30) y 0.006 mg/L (años de cierre 31-38), mientras que los valores máximos variaron entre 0.005 (años de operaciones 0-27) y 0.006 mg/L (años de operaciones 28-30; años de cierre 31-38, 39-42 y &gt;43). La concentración de la calidad del agua de línea base en esta ubicación es de 0.003 mg/L.</li></ul> <p>Las concentraciones de cobre previstas tienden a ser más altas durante las fases de cierre y post-cierre que durante la fase de operación de la mina.</p> |
| molibdeno | valor guía CCME para uso agrícola (regadío) | El valor guía CCME más bajo se basa en el uso agrícola (riego: de 0.01 a 0.05 mg/L). El límite superior (0.05 mg/L) de los criterios agrícolas es para uso a corto plazo sólo en suelos ácidos. La concentración de agua prevista más alta para el molibdeno es de 0.02 mg/L. La guía CCME para agua para el ganado es de 0.5 mg/L y para la protección de vida acuática de agua dulce es de 0.073 mg/L. | El valor guía CCME para uso agrícola se basa en el riesgo asociado con la recolección de cultivos de los suelos para el ganado que consume alimento contaminado, más que para los cultivos mismos. Las plantas toleran niveles de tejido de molibdeno de varios cientos de mg/kg sin efectos adversos (Gupta y Lipsett 1981). La concentración de molibdeno más alta pronosticada en el agua (0.02 mg/L) dentro del área de estudio se encuentra por debajo del valor guía CCME para la vida acuática en agua dulce (0.073 mg/L), por lo que se prevé que las concentraciones previstas tendrán un impacto insignificante en la vida acuática de agua dulce.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

La concentración de línea base promedio del cadmio en el área de estudio principal fue de 0.1 µg/L. Las concentraciones previstas de calidad del agua también fueron evaluadas contra el valor LOEC más sensible de 0.17 µg/L. Las concentraciones de cadmio previstas excedieron 0.17 µg/L sólo durante las fases de operaciones y cierre en tres nodos en la cuenca hidrográfica del Río Caimito (W-3, W-3-2 y W8), con concentraciones previstas que fluctuaban entre 0.2 y 0.3 µg/L (Tabla 2-1). Estas concentraciones previstas son menores al doble de la LOEC para la especie más sensible utilizada en el desarrollo de los valores guía, y por lo tanto, las concentraciones de cadmio previstas representan un riesgo de efectos adversos relativamente bajo.

- **Cobre** – El valor guía CCME (2008) para el cobre en agua blanda (0.002 mg/L) se basa en un valor recomendado por Demayo y Taylor (1981), y no se considera que represente los últimos avances científicos relacionados con la toxicología del cobre. Se ha incorporado avances científicos más recientes en el Criterio de Calidad de Agua de la USEPA (0.0023 mg/L), valor que se basa en la aplicación del Modelo del Ligando Biótico (BLM, por sus siglas en inglés) (USEPA 2007). El BLM es un modelo de biodisponibilidad de metales que utiliza las características de las aguas receptoras para calcular Criterios Continuos Crónicos (CCC) específicos del área. Con el empleo del BLM, se desarrolló los siguientes valores CCC para el cobre disuelto: 0.0016 mg/L para la cuenca hidrográfica del Río Petaquilla, 0.0022 mg/L para la cuenca hidrográfica del Río San Juan, y 0.0043 mg/L para la cuenca hidrográfica del Río Caimito. Estos valores específicos para las cuencas hidrográficas son similares en magnitud a los valores guía para el cobre total adoptados por la CCME, pero, al considerar los valores CCC, se puede obtener una base para la evaluación de las concentraciones de cobre disuelto, que se espera sean menores a las concentraciones de cobre total. La comparación de las concentraciones de cobre total con los valores CCC representa, por lo tanto, una evaluación conservadora de la posibilidad de que haya efectos adversos en la vida acuática. El grado de conservadurismo inherente en esta comparación depende de la fracción de cobre total que se encuentre en la fase disuelta.

Las concentraciones de cobre total previstas excedieron los valores CCC en varios nodos en las cuencas hidrográficas de los ríos Petaquilla y San Juan/Botija, aunque no excedieron las concentraciones de línea base en estas ubicaciones. En la cuenca hidrográfica del Río Caimito, las concentraciones de cobre total previstas excedieron tanto los valores CCC como las concentraciones de línea base en los nodos W3, W3-2, W8, W7, W13 y W20 durante las fases de operaciones y cierre (Tabla 2-1). Las concentraciones de cobre total previstas en estos nodos en la cuenca hidrográfica del Río Caimito (concentraciones promedio de hasta 0.01 mg/L, concentraciones máximas de hasta 0.02 mg/L) representan excedencias relativamente importantes de los valores CCC (de 0.0016 a 0.0043 mg/L) y de las concentraciones de línea base (0.003 mg/L). Cabe resaltar que la comparación de las concentraciones de cobre previstas (cobre total) con los valores CCC (cobre disuelto) que se hace en esta evaluación se considera bastante conservadora. El riesgo potencial que representan las concentraciones previstas de cobre es incierto. Esta incertidumbre no se puede resolver en este momento, puesto que la fracción total de cobre prevista que podrá estar presente en la fase disuelta se desconoce.

- **Molibdeno** – El criterio reglamentario más bajo fue el valor guía CCME (2008) para uso agrícola, el cual se basa en el riesgo asociado con la recolección de cultivos de los suelos destinados para el ganado que consume alimento contaminado, más que para los cultivos mismos. Las plantas toleran niveles de tejido de molibdeno de varios cientos de mg/kg sin llegar a tener efectos adversos (Gupta y Lipsett 1981). La concentración más alta de agua pronosticada (0.02 mg/L) en el área del Proyecto se encuentra por debajo del valor guía para la vida acuática en agua dulce (0.073 mg/L), por lo que se prevé que las concentraciones de molibdeno previstas tendrán impactos insignificantes en la vida acuática de agua dulce.

### **3 REVISIÓN DEL MATERIAL BIBLIOGRÁFICO CIENTÍFICO RELEVANTE**

Para evaluar con mayor detalle la incertidumbre inherente de la aplicación de los criterios de análisis norteamericanos en la evaluación de las concentraciones de aluminio y cobre en las aguas superficiales panameñas, se revisó el material bibliográfico científico relevante. El Consejo Canadiense de Ministros del Ambiente (CCME 2008) y la Agencia de Protección Ambiental de Estados Unidos (USEPA 1988, 2007) han desarrollado valores guía de calidad del agua para el aluminio y el cobre, con miras a proteger la vida acuática. Estas guías se elaboraron para proteger las especies norteamericanas más sensibles y, por lo tanto, no es raro utilizarlas para evaluar ambientes de aguas frías y aguas cálidas. Por ejemplo, el Departamento de Protección Ambiental de la Florida indicó que los estándares de calidad del agua de Florida se basan en los criterios de la USEPA, y observó que los datos utilizados para obtener los criterios de calidad del agua incluyen cierto número de peces de aguas cálidas encontrados en este estado (N. Roth, comunicación personal, Departamento de Protección Ambiental de Florida, 10 de febrero de 2010).

A pesar de la práctica habitual de aplicar criterios de análisis norteamericanos a los ambientes tropicales, existen ciertas diferencias entre los sistemas templados y tropicales que podrían causar incertidumbre al momento de elaborar las conclusiones relevantes de las evaluaciones realizadas. Los aspectos principales incluyen la comparabilidad de la sensibilidad de las especies a los diferentes climas, los efectos de las diversas características del agua en la toxicidad del metal y la diferencias existentes en los niveles naturales de línea base de los metales que podrían producir diferentes formaciones de especies y/o diferentes sensibilidades en las mismas.

Existen pocos estudios que han comparado las sensibilidades existentes entre las biotas templadas y las tropicales. Dyer et al. (1997) llevó a cabo una evaluación de estudios de toxicidad aguda en algunos químicos, descubriendo que las especies de peces de agua fría eran las más sensibles, seguidas por las especies templadas y finalmente las tropicales. La evaluación utilizó datos de toxicidad aguda, pero no se sabe si la sensibilidad a la exposición crónica tenía un patrón similar. No obstante, los resultados de esta evaluación sugieren que el usar las guías obtenidas de especies de agua fría o templada puede ofrecer una evaluación conservadora de la posibilidad de la existencia de efectos adversos en las especies tropicales.

Los efectos de las características del agua en la toxicidad del aluminio y el cobre son bastante conocidos. Se ha informado que la toxicidad del aluminio y el cobre varían considerablemente según la alcalinidad, dureza, pH, materia orgánica disuelta y temperatura (Gensemer y Playle 1999) del agua. Así, es posible que estas características puedan influenciar la posibilidad de que haya efectos adversos

causados por el aluminio y el cobre en el área de estudio principal, ya que los arroyos en esta zona tienden a ser cálidos, claros (es decir, con un contenido bajo de carbono orgánico disuelto) y circumneutros, pero con una capacidad de amortiguamiento baja (es decir, pobres en iones y probablemente susceptibles a los cambios que pudieran existir en el pH).

Existe una relación entre la temperatura del agua y la toxicidad: mientras mayor sea la temperatura, mayor será la toxicidad para algunas especies (pero no todas; Carvalho y Fernandes 2006), aunque, por lo general, este incremento en la toxicidad está relacionado al metabolismo de las especies, es decir, si la especie tiene un mayor metabolismo, entonces, tendrá una mayor absorción y distribución de tóxicos (Dyer et al. 1997). Este mismo autor observó que, con frecuencia, las conclusiones a las que se llega respecto a la toxicidad relacionada con la temperatura no consideran el ambiente térmico del hábitat de una especie. Por lo tanto, se anticipa que la posibilidad de un aumento en la toxicidad del aluminio y el cobre debido solamente a la temperatura del agua sería baja.

Por otro lado, los estudios realizados confirmaron los efectos del pH en la toxicidad del aluminio y el cobre, los cuales se obtienen tomando como base los valores guía de la calidad del agua de CCME (CCME 1998) y los criterios de la calidad del agua de USEPA (USEPA 2007). La mayoría de los estudios han relacionado la toxicidad del aluminio con condiciones ácidas, ya que el aluminio se vuelve más tóxico para la biota acuática en agua ácida (Gensemer y Playle 1999). Algunos de estos estudios incluyeron especies tropicales. Un estudio sobre el pez neotropical de agua dulce *Prochilus lineatus* en particular descubrió que, para alterar la capacidad osmorreguladora de la especie (Camargo et al. 2009) era necesario que se viera agudamente expuesta a concentraciones de aluminio disuelto de 196 µg/L (valores que son considerablemente mayores a los valores de análisis de CCME y USEPA). No obstante, no se cuenta con estudios que traten acerca de exposición crónica, por lo que no está muy claro cuáles serían las concentraciones que podrían causar efectos crónicos.

También se cuenta con una considerable cantidad de información respecto a los efectos del carbono orgánico disuelto (COD) en la toxicidad del aluminio y el cobre. La concentración del COD tiene una fuerte influencia en el criterio calculado por el BLM (USEPA 2007), debido a la capacidad que tiene el COD de aglutinar cobre disuelto y evitar que provoque efectos tóxicos. Algunos investigadores han sugerido efectos similares del COD en la toxicidad del aluminio, como por ejemplo Roy et al. (2000), quien identificó niveles de base de aluminio total en el Río Saguenay, Canadá, que excedieron los valores guía de la CCME (100 µg/L) y el USEPA (87 µg/L) para el pH circumneutral. En el estudio, se midió los niveles de toxicidad en la especie *Ceriodaphnia dubia* y en las larvas de carpitas cabezonas (*Pimephales promelas*) que habitaban en el ambiente receptor, el cual recibía descargas de una planta reductora

de aluminio primario. A pesar de que los niveles de aluminio mostraron concentraciones de hasta 596 µg/L en el agua receptora, no hubo efectos considerables en la reproducción de la *C. dubia*, ni tampoco en el crecimiento de las carpitas cabezonas o en la supervivencia de ninguno de los dos organismos (Roy et al. 2000). Es necesario recalcar que, en este río, una buena parte del aluminio estaba dirigida a la materia orgánica, con la intención de reducir los impactos de la toxicidad del aluminio (Winter et al. 2005). Finalmente, Roy et al. (2000) sostuvieron que las evaluaciones basadas en el aluminio total sobreestimarían el riesgo que pudiera causar este elemento al medio ambiente, por lo que sugirieron que se exprese un valor guía más apropiado como aluminio inorgánico monomérico, que es la forma asociada a la toxicidad en organismos acuáticos.

En general, las aguas superficiales del área de estudio principal son bajas en COD, lo cual indica que tienen una capacidad limitada para aglutinar cobre disuelto y aluminio. La dureza y la alcalinidad también tienden a ser bajas en esta zona, aunque el pH tiende a ser circumneutral. En general, el pH circumneutral está asociado con la baja toxicidad del aluminio y el cobre, aunque la baja capacidad de amortiguamiento de estas aguas también podría indicar una posible susceptibilidad a la acidificación. Por lo tanto, si se produjera un cambio en las condiciones ácidas del agua, podría haber un aumento en la toxicidad del aluminio y el cobre.

## 4 CONCLUSIONES Y RECOMENDACIONES

El presente estudio identificó el aluminio y el cobre como dos sustancias cuyas posibles concentraciones en el agua de ciertas ubicaciones podrían representar un riesgo de efectos adversos en la vida acuática. No obstante, la posibilidad de que las concentraciones previstas afecten la vida acuática aún es incierta, por las siguientes razones:

- Las concentraciones de línea base del aluminio y el cobre en el área de estudio principal fueron mayores a los valores del análisis reglamentario. Esto sugiere dos situaciones: que cualquier nivel natural de estas sustancias en la región es tóxico en la vida acuática; o que la excedencia de los valores resultantes del análisis en realidad no indica que haya la posibilidad de causar efectos adversos. Tomando como base el material bibliográfico revisado, se puede considerar que la última explicación es la más probable. Los valores del análisis probablemente no reflejen con precisión la sensibilidad que pueda tener la biota panameña de agua dulce al aluminio y cobre.
- El aumento previsto en la concentración de aluminio en el agua es bajo en relación con la precisión con la que se modelan estos pronósticos y, por lo tanto, no se sabe con certeza si en realidad ocurrirá un aumento que se pueda medir.
- La evaluación del cobre se basó conservadoramente en una comparación de cobre total (la base de las concentraciones previstas) con cobre disuelto (la base del Criterio Crónico Continuo). En este momento, no es posible pronosticar cuál será la fracción del cobre que estará en forma disuelta y, por lo tanto, no se sabe con certeza si el cobre total previsto representa un riesgo de efectos adversos.

Dadas las consideraciones descritas anteriormente, se concluye que las concentraciones previstas de COPC en el agua indican una *posibilidad* de efectos adversos, pero que la *probabilidad* de efectos adversos es muy incierta. Lamentablemente, en la actualidad no existen datos o conocimiento científico suficiente para resolver esta incertidumbre del todo. Por lo tanto, se recomienda que MPSA se comprometa a desarrollar un Plan de Gestión de Calidad del Agua que pueda implementarse durante las fases de desarrollo y operación de la mina, hasta un grado tal que evite impactos inaceptables en la vida acuática. En general, las mayores concentraciones previstas de COPC en el agua no ocurren hasta después del cierre de la mina, lo cual indica que habrá un período de oportunidad para perfeccionar la evaluación de efectos potenciales e implementar el plan de mitigación, según sea necesario.

Al tener un Plan de Manejo de Calidad del Agua para el Proyecto, se podría definir un programa de monitoreo y una serie de reglas de decisión que podrían especificar las

acciones a tomar según los resultados obtenidos en las actividades de monitoreo. Los componentes de un Plan de Manejo de Calidad del Agua podrían incluir:

- un programa de monitoreo diseñado para detectar cualquier cambio relacionado con el Proyecto en la calidad del agua;
- el desarrollo de una o más concentraciones de referencia asociadas con los efectos adversos potenciales;
- investigaciones confirmatorias de la calidad del agua, a ejecutarse en caso que el monitoreo indique una desviación de las condiciones de la calidad del agua de línea base;
- investigaciones de tendencias, para evaluar si las desviaciones de las condiciones de línea base indican un potencial de excedencia de las referencias de efectos; y
- una secuencia (por niveles) de las acciones de gestión a seguir, las cuales deberán ejecutarse sólo de ser necesario, para evitar impactos inaceptables en la vida acuática.
